Finding Rost's Solution

Optimality 00000000000 Heston-Nandi & Asymptotic Optimality

Conclusions

Financial Setting

- Option priced on an asset S_t
- Dynamics of S_t unspecified, but suppose paths are continuous, and we see prices of call options at all strikes K and at maturity time T
- Assume for simplicity that all prices are discounted this won't affect our main results
- Under risk-neutral measure, S_t should be a (local-)martingale, and we can recover the law of S_T at time T from call prices C(K).... Skorokhod Embedding Problem... David's talks...

・ 日 ・ ・ 雪 ・ ・ 目 ・ ・ 日 ・

Finding Rost's Solution

Optimality 00000000000 Heston-Nandi & Asymptotic Optimality

Conclusions

Variance Options

• We may typically suppose a model for (discounted) asset prices of the form:

$$\frac{dS_t}{S_t} = \sigma_t dW_t,$$

where W_t a Brownian motion.

- the volatility, σ_t , is a locally bounded, progressively measurable process
- Want to consider options on variance.
- For example, a variance swap pays:

$$\int_0^T \left(\sigma_t^2 - \bar{\sigma}^2\right) dt$$

where $\bar{\sigma}$ is the 'strike'. Dupire (1993) and Neuberger (1994) gave a simple replication strategy for such an option. (More recently, Davis-Obłój-Ramal, 2013).

Finding Rost's Solution

Optimality

Heston-Nandi & Asymptotic Optimality

Conclusions o

Hedge of Variance Swap

• Dupire's hedge: Itô implies

$$d\left(\ln S_{t}\right) = \sigma_{t} \, dW_{t} - \frac{1}{2}\sigma_{t}^{2} \, dt$$

- Hold portfolio short 2 contracts paying ln(S_T), long 2/S_t units of asset
- At time T, portfolio will be worth (up to constant) $\int_0^T \sigma_t^2 dt$
- Note that the only modelling assumption here is that the volatility process exists!
- Note also that $\langle \ln S \rangle_T = \int_0^T \sigma_t^2 dt$, where $\langle \cdot \rangle_t$ is quadratic variation.

・ 日マ ・ 雪マ ・ 日マ ・ 日マ

Finding Rost's Solution

Optimality 00000000000 Heston-Nandi & Asymptotic Optimality

Conclusions o

Variance Options

• A variance call is an option paying:

$$(\langle \ln S \rangle_T - K)_+$$

- More general options of the form: $F(\langle \ln S \rangle_T)$.
- E.g.: volatility swap, payoff:

$$\sqrt{\langle \ln S \rangle_T} - K.$$

• More generally, can consider payoffs dependent on weighted realised variance:

$$\mathsf{RV}_T^\lambda = \int_0^T \lambda(S_t) \, d \, \langle \ln S \rangle_t = \int_0^T \lambda(S_t) \sigma_t^2 dt.$$

• E.g.: options on corridor variance or a gamma swap:

$$\int_0^T \mathbf{1}_{\{S_t \in [a,b]\}} d\langle \ln S \rangle_t, \quad \int_0^T S_t d\langle \ln S \rangle_t.$$

inding Rost's Solution

Optimality 00000000000 Heston-Nandi & Asymptotic Optimality

Conclusions

Options on (weighted) realised variance

- Let $\lambda(x)$ be a strictly positive, continuous function, $\tau_t := RV_T^{\lambda} = \int_0^t \lambda(S_s) \sigma_s^2 ds$ and A_t such that $\tau_{A_t} = t$.
- Then $\widetilde{W}_t = \int_0^{A_t} \sigma_s \lambda(S_s)^{1/2} dW_s$ is a BM w.r.t. $\widetilde{\mathcal{F}}_t = \mathcal{F}_{A_t}$, and if we set $\widetilde{X}_t = S_{A_t}$, we have:

$$d\widetilde{X}_t = \widetilde{X}_t \lambda(\widetilde{X}_t)^{-1/2} d\widetilde{W}_t.$$

- \widetilde{X}_t is now a diffusion on natural scale
- $(\widetilde{X}_{\tau_T}, \tau_T) = (S_T, RV_T^{\lambda})$
- Knowledge of $\mathcal{L}(\mathcal{S}_T) \implies \mathcal{L}(\widetilde{X}_{\tau_T}).$

Finding Rost's Solution

Optimality 00000000000 Heston-Nandi & Asymptotic Optimality

Conclusions

Variance Call

 Finding bound on price of variance call with given call prices is equivalent to:

min/maximise: $\mathbb{E}(\tau - K)_+$ subject to: $\mathcal{L}(X_{\tau}) = \mu$

where μ is a given law.

- These are (essentially) the problems solved by Root's and Rost's Barriers!
- Rost (1971) proved the existence of a filling scheme stopping time for a general class of processes. Chacon (1985) showed that the filling scheme was indeed a reversed barrier under some assumptions on the process, and proved optimality.
- The connection to Variance options has been observed by a number of authors: Dupire ('05), Carr & Lee ('09), Hobson ('09).

Rost's Solution: Class of possible processes

Suppose

$$d\widetilde{X}_t = \widetilde{X}_t \lambda(\widetilde{X}_t)^{-1/2} d\widetilde{W}_t,$$

where λ is in the set $\mathcal{D} \subseteq \mathcal{C}(I; \mathbb{R})$ such that

- λ(x) is strictly positive,
- \widetilde{X} is a regular diffusion on *I*,
- with transition density p(t, x, y) with respect to Lebesgue
- such that, for any x₀ ∈ *I*, c > 0, open set A containing x₀ and ε > 0, there exists δ > 0 such that

$$|(p(t,x,x_0)-p(s,x,x_0))x_0^2\lambda(x_0)^{-1}|<\varepsilon$$

whenever $|s - t| < \delta$ and either $x_0 \notin A$ or t > c. (Chacon's Equicontinuity condition)

Conclusions

Rost's Solution

Theorem (Rost & Chacon)

Suppose μ and ν are probability measures on I with $\nu \leq_{cx} \mu$, and $\lambda \in \mathcal{D}$ with $\widetilde{X}_0 \sim \nu$:

- 1. *if* μ and ν have no mass in common, then there exists a reversed barrier D such that $\widetilde{X}_{\tau_D} \sim \mu$;
- 2. if μ and ν have mass in common, then (on a possibly enlarged probability space) there exists a random variable $S \in \{0, \infty\}$, and reversed barrier D, such that $\widetilde{X}_{\tau_D \wedge S} \sim \mu$.

Moreover, in both cases, the resulting embedding maximises $\mathbb{E}F(\sigma)$ over all stopping times σ with $\widetilde{X}_{\sigma} \sim \mu$ and $\mathbb{E}\sigma = \mathbb{E}\tau_D \wedge S < \infty$, for any convex function F on $[0, \infty)$.

Finding Rost's Solution

Optimality 0000000000 Heston-Nandi & Asymptotic Optimality

Conclusions

Characterising the Barrier

Suppose $I = (0, \infty)$, $\lambda \in C^{1}(I) \cap \mathcal{D}$ and, $|\lambda(x)^{-1}|$ and $|\lambda'(x)\lambda(x)^{-2}x|$ are bounded on $(0, \infty)$.

Theorem

Suppose D is Rost's reversed barrier. Then $u(x,t) = U_{\mu}(x) + \mathbb{E}^{\nu} |x - \widetilde{X}_{t \wedge \tau_D \wedge S}|$ is the unique bounded viscosity solution to:

$$rac{\partial u}{\partial t}(x,t) = \left(rac{\sigma(x)^2}{2}rac{\partial^2 u}{\partial x^2}(x,t)
ight)_+ u(0,x) = \mathrm{U}_\mu(x) - \mathrm{U}_
u(x).$$

Moreover, given a solution u, a reversed barrier D which solves the SEP can be recovered by $D = \{(x, t) : u(x, t) > u(0, t)\}.$

Finding Rost's Solution

Optimality 00000000000 Heston-Nandi & Asymptotic Optimality

Conclusions

Optimality

The additional T in the construction means that we cannot construct a pathwise inequality for all cases, even though we can prove optimality in general by a limiting argument.

However the functions G_T , H_T , Z_T can be interpreted in the limit provided we can find $\alpha > 1$ such that for *t* large:

$$C \geq F'(t) \geq C - O(t^{-\alpha}).$$

In this case, we do indeed have a pathwise inequality, and can derive a pathwise inequality

In C. & Wang, we provided a similar proof of optimality for Root's embedding, where the dependence on T is no longer necessary, and the proof will go through in general.

and $H_T(X_t)$ can be replicated by holding a suitable portfolio of the traded calls.

Moreover, in the case where $\tau = \tau_D$, we get equality.

Optimality 000000000000 Heston-Nandi & Asymptotic Optimality

Conclusions o

Forward Starting options

More generally, we can consider forward starting options, whose payoff is $F(\langle \ln S \rangle_{t_2} - \langle \ln S \rangle_{t_1})$ if we know the call prices at times t_1, t_2 .

Construct the barrier where the initial law is now non-trivial: use the law at time t_1 instead.

As well as the portfolio of calls at time t_2 , and the dynamic trading strategy as above, we must also be able to replicate $G(\tilde{X}_{t_1}, 0)$. However, this can be done using the calls with maturity t_1 .

Conclusions

Practical implementation

Well-known results on viscosity solutions mean that we can use standard discretisation methods (Barles-Souganidis, c.f. Oberhauser & dos Reis) for PDEs to find *u*, and thus the reversed barrier.

In fact, with a little extra work, we can even use implicit methods — for Rost, this seems necessary (lots of detail at the start!)

Can then compute the hedging strategies, and the upper and lower price bounds.

Conclusions o

Numerical Implementation

Payoff: F'(t) = 2(t ∧ K), K ≈ 0.2. Under the incorrect model.

Finding Rost's Solution

Optimality 00000000000 Heston-Nandi & Asymptotic Optimality •0000 Conclusions o

Heston-Nandi model

The Heston model is given (under the risk-neutral measure) by:

$$dS_t = rS_t dt + \sqrt{v_t}S_t dB_t,$$

$$dv_t = \kappa(\theta - v_t) dt + \xi \sqrt{v_t} d\widetilde{B}_t,$$

where B_t and B_t are Brownian motions with correlation ρ . The Heston-Nandi model is the restricted case where $\rho = -1$, and so $\tilde{B}_t = -B_t$. Note that $v_t = \sigma_t^2$ in our previous notation, so we are interested in options on $\int_0^T v_t dt$

inding Rost's Solution

Optimality 00000000000 Heston-Nandi & Asymptotic Optimality

Conclusions

Heston-Nandi and Barrier stopping times Using Itô's Lemma, we know

$$d(\log(e^{-rt}S_t)) = -\frac{1}{2}v_t dt + \sqrt{v_t} dB_t$$
$$= \left(\frac{\kappa\theta}{\xi} - \left(\frac{\kappa}{\xi} + \frac{1}{2}\right)v_t\right) dt - \frac{1}{\xi}dv_t.$$

Solving, we see that

$$\log\left(\frac{\mathrm{e}^{-rT}S_T}{S_0}\right) = \frac{1}{\xi}(v_0 - v_T) + \frac{\kappa\theta}{\xi}T - \left(\frac{\kappa}{\xi} + \frac{1}{2}\right)\int_0^T v_t\,dt.$$

Since v_T is mean reverting, $(v_T - v_0) \approx (\theta - v_0)$ will be comparatively small for large *T*. In this case, we can write:

$$\int_{0}^{T} v_t \, dt \approx R_T (e^{-rT} S_T) = \left(\frac{\kappa}{\xi} + \frac{1}{2}\right)^{-1} \left[\frac{\kappa\theta}{\xi} T + \log\left(\frac{S_0}{e^{-rT} S_T}\right)\right] \xrightarrow{\text{BATH}}$$

Theorem

Let M > 0 and suppose $\xi, \theta, \kappa, r > 0, \xi \neq 2\kappa$ are given parameters of a Heston-Nandi model, \mathbb{Q}^{HN} . Suppose \mathcal{Q}_T is the class of models \mathbb{Q} satisfying $\mathbb{E}^{\mathbb{Q}^{HN}}(S_T - K)_+ = \mathbb{E}^{\mathbb{Q}}(S_T - K)_+$ for all $K \ge 0$.

Then there exists a constant κ , depending only on M and the parameters of the Heston-Nandi model, such that for all convex, increasing functions F(t) with suitably smooth derivative f(t) = F'(t) such that $f(t), f'(t) \le M^*$, and for all $T \ge 0$

$$\mathbb{E}^{\mathbb{Q}^{HN}} F\left(\langle \log S \rangle_{\mathcal{T}} \right) \leq \inf_{\mathbb{Q} \in \mathcal{Q}_{\mathcal{T}}} \mathbb{E}^{\mathbb{Q}} F\left(\langle \log S \rangle_{\mathcal{T}} \right) + \kappa.$$

Heston-Nandi is asymptotically optimal.
