

# Oscillators and Resonance

harmonic oscillator :

$$\ddot{x} + \omega^2 x = 0$$

$$\begin{cases} \dot{x} = y \\ \dot{y} = -\omega^2 x \end{cases}$$

with solution  $\begin{cases} x(t) = A \cos \omega t + B \sin \omega t \\ y(t) = -A \omega \sin \omega t + B \omega \cos \omega t. \end{cases}$

All solutions are periodic except a stationary point of center type at the origin.

pendulum

$$\ddot{x} + \omega^2 \sin x = 0$$

Newton's equation becomes

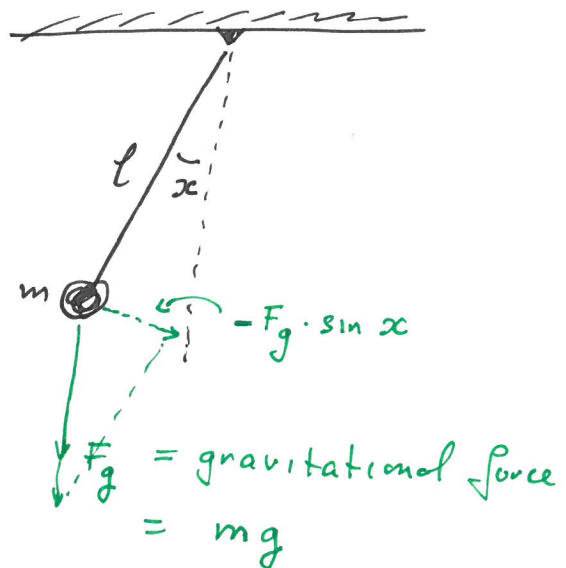

force  $\downarrow$  acceleration  
 $F = ma$   
 $\uparrow$  mass

$$-F_g \sin x = ml \ddot{x}$$

Insert  $F_g = mg$   
and divide by  $ml$  :

$$\ddot{x} + \left(\frac{g}{l}\right) \sin x = 0$$

$= \omega^2 = \text{frequency squared.}$

gravitational constant

$\approx 9.8 \frac{m}{sec^2}$  on Earth

Different derivation via preservation of energy:

$$E_{kin} = \frac{1}{2} m v^2 = \frac{1}{2} m (l \dot{x})^2 \quad \text{kinetic energy}$$

$$E_{pot} = \text{Const} + mgh = \underbrace{\text{Const} - mgl \cos x}_{V(x)} \quad \text{potential energy}$$

$$0 = \dot{E} = \frac{d}{dt} (E_{kin} + E_{pot})$$

$$= ml^2 \dot{x} \ddot{x} + mgl \sin x$$

Divide by  $ml^2 \dot{x}$

$$0 = \ddot{x} + \frac{g}{l} \sin x$$

no explicit formulas  
for the solutions known

phase portrait  
of pendulum

damped pendulum

$$\ddot{x} + r \dot{x} + \omega^2 \sin x = 0$$

friction term,  $r > 0$

For the damped pendulum, energy dissipates:

$$\begin{aligned} \dot{E} &= \frac{d}{dt} (E_{kin} + E_{pot}) = \frac{d}{dt} \left( \frac{1}{2} m (l \dot{x})^2 + (mgl - mg l \cos x) \right) \\ &= m l^2 \dot{x} \ddot{x} + mgl \sin x \dot{x} \\ &= m l^2 \dot{x} \left( \ddot{x} + \left( \frac{g}{l} \right) \sin x \right) \\ &= m l^2 \dot{x} (-r \dot{x}) = -m l^2 g r \dot{x}^2 \leq 0 \end{aligned}$$

NB The damped harmonic oscillator can be solved explicitly.

$$\ddot{x} + r \dot{x} + \omega^2 x = 0$$

Ansatz:  $x(t) = e^{\lambda t}$   $\times \omega^2$

$\dot{x}(t) = \lambda e^{\lambda t}$   $\times r$

$\ddot{x}(t) = \lambda^2 e^{\lambda t}$   $\times 1$   $+$

---

$(\omega^2 + r\lambda + \lambda^2) e^{\lambda t} = 0$

Hence  $\lambda = -\frac{r}{2} \pm \sqrt{\left(\frac{r}{2}\right)^2 - \omega^2}$ , with solution

$$\begin{aligned} x(t) &= A e^{-\frac{r}{2} + i\sqrt{\omega^2 - \left(\frac{r}{2}\right)^2} t} + B e^{-\frac{r}{2} - i\sqrt{\omega^2 - \left(\frac{r}{2}\right)^2} t} \\ &= e^{-\frac{r}{2} t} \left( A' \cos \sqrt{\omega^2 - \left(\frac{r}{2}\right)^2} t + B' \sin \sqrt{\omega^2 - \left(\frac{r}{2}\right)^2} t \right) \end{aligned}$$

for small friction:  
 $\frac{r}{2} < |\omega|$

# Driven oscillators

$$\ddot{x} + r\dot{x} + \omega^2 x = A \cos t$$

friction term

driving force (also oscillating)

describes the motion of a child on a swing pushed by its parent, but also the behaviour of a radio antenna.

For simplicity, we give it a proper linear term (i.e. not  $\omega^2 \sin x$ ), so this is a 2<sup>nd</sup> order inhomogeneous linear ODE.

The homogeneous solution (with RHS = 0) was just given. To solve the entire ODE we have to find a particular solution and add it to the homogeneous solution.

Ansatz

$$x_{\text{par}}(t) = p \cos t + q \sin t \quad \times \omega^2$$

$$\dot{x}_{\text{par}}(t) = -p \sin t + q \cos t \quad \times r$$

$$\ddot{x}_{\text{par}}(t) = -p \cos t - q \sin t \quad \times 1$$

---

$$A \cos t = (\omega^2 p + r q - p) \cos t + (\omega^2 q - r p - q) \sin t$$

$$\Rightarrow \begin{cases} q = \frac{r p}{\omega^2 - 1} \\ p = \frac{A + r q}{\omega^2 - 1} \end{cases}$$

Driven oscillator continued

- 5 -

$$\ddot{x} + r\dot{x} + \omega^2 x = A \cos t$$

$$\begin{cases} q = \frac{r p}{\omega^2 - 1} \\ p = \frac{A - r q}{\omega^2 - 1} \end{cases} \Rightarrow p = \frac{A}{\omega^2 - 1 + r^2}$$

Hence the amplitude of the particular solution  $x_{\text{par}}$  is very large if both friction  $r \approx 0$  and  $\omega^2 \approx 1$

resonance.

In the extreme case of a frictionless driven oscillator:

$$\ddot{x} + \omega^2 x = A \cos t$$
 the same

method with adjusted Ansatz gives:

$$\text{Ansatz: } x_{\text{par}}(t) = p \sin t + q t \sin t \quad \times \omega^2$$

$$\dot{x}_{\text{par}}(t) = p \cos t + q \sin t + q t \cos t \quad \times 0$$

$$\ddot{x}_{\text{par}}(t) = -p \sin t + 2q \cos t - q t \sin t \quad \times 1$$

$$A \cos t = 2q \cos t$$

$$\text{so } x_{\text{par}}(t) = \frac{A t}{2} \cos t$$

but this solution is unbounded over time!

### Coupled oscillators

$$\begin{cases} \ddot{x}_1 + \omega_1^2 x_1 = \varepsilon f_1(x_2) \\ \ddot{x}_2 + \omega_2^2 x_2 = \varepsilon f_2(x_1) \end{cases}$$

Naturally there can be more than two oscillators and friction terms are left out for simplicity

If there is no coupling i.e.  $\varepsilon = 0$  then the solutions are

$$\begin{cases} x_1(t) = A_1 \cos(t + t_1) \\ x_2(t) = A_2 \cos(t + t_2) \end{cases}$$

Consider a Poincaré section

$$\Sigma = \{x_1 = A_1\},$$

then  $(x_1(t), x_2(t)) \in \Sigma$  if  $t = \frac{2\pi k}{\omega_1} - t_1$   $k \in \mathbb{Z}$

and then  $x_2(t) = A_2 \cos\left(\underbrace{2\pi k \frac{\omega_2}{\omega_1} - \omega_2 t_1 + t_2}_{u_k}\right)$

i.e.  $x_2(t) = A_2 \cos(u_k)$  for  $u_k = R_\alpha^k(u_0)$   $u_0 = t_2 - \omega_2 t_1$

and  $R_\alpha$  is the rotation with angle  $\alpha = \frac{\omega_2}{\omega_1}$  (usually  $\notin \mathbb{Q}$ )

Also assume  $\omega_2 \approx \omega_1$  so

$$\frac{\omega_2}{\omega_1} \bmod 1 \equiv \delta \approx 0$$

If there is coupling, i.e.  $\varepsilon > 0$ , then  $R_\alpha$  becomes  $R_{\alpha, \varepsilon}$ , some non-linear perturbation of  $R_\alpha$ . If  $\delta$  is small compared to  $\varepsilon$ , then  $R_{\alpha, \varepsilon}$  is likely to have a fixed point

# Oscillators with parametric resonance

time dependent,  
usually periodic - 7 -

$$\ddot{x} + \omega^2(t) \sin x = 0$$

This models the behaviour of a person on a swing keeping it swinging by shifting his body back and forth.

This can make the stationary point  $x(t) \equiv 0$  unstable and the stationary point  $x(t) \equiv \pi$  stable.
