Communicated by F.-O. Speck

SUMMARY

KEY WORDS: scattering; wedge; Limiting Amplitude principle

1. INTRODUCTION

This paper is a continuation of our paper [1], but the exposition is independent. In Reference [1], we have proved the Sommerfeld–Malyuzhinets-type integral representation and uniqueness of the solution of a nonstationary scattering problem by a wedge using the method of the complex characteristics [2].

Here we give the next steps in our program of mathematical foundation of scattering by wedges [1]. Namely, we prove the existence of the solution and the Limiting

Amplitude principle. We show that the Sommerfeld–Malyuzhinets-type integral, obtained in References [1,3], belongs to an appropriate functional space, and the Limiting Amplitude principle holds.

For the corresponding stationary diffraction problem, the integral representation of the solution appeared first in the Sommerfeld paper [4], for the diffraction by a half-plane, and in Malyuzhinets paper [5] for a general angle (see also References [5–8] and a survey [9]). However, its relations to the corresponding nonstationary problem has been never done rigorously.

The explicit formulas for the scattering of the incident wave of the Heaviside type were obtained in the papers [10,11]. This case is the particular case of the problem considered in this paper when the frequency is zero, and the profile function is the Heaviside one. The method [10,11] is based on the special ‘polar coordinates’ in $xyt$-space. The problem also was considered in Reference [12], where the explicit formulas were obtained using the method of the ramified solutions of the wave equations. The uniqueness and the relation with the corresponding stationary diffraction problem have not been considered.

For the first time, the Limiting Amplitude principle has been considered in Reference [13] for a concrete solution, without a detailed analysis of its smoothness and uniqueness. We give a detailed analysis of the existence and uniqueness of a solution from an appropriate functional class. The solution is smooth if the profile function is smooth. Furthermore, we prove the Limiting Amplitude principle for the solution which is defined uniquely by its features, and not by an explicit formula.

The paper concerns two-dimensional scattering of plane waves by a wedge

$$W := \{ y = (y_1, y_2) : y_1 = \rho \cos \theta, \ y_2 = \rho \sin \theta, \ \rho \geq 0, \ 0 \leq \theta \leq \phi \}$$

of an opening $\phi \in (0, \pi)$. We consider an incident plane wave $u_{in}(y,t)$ of the form

$$u_{in}(y,t) = e^{i(k_0 \cdot y - \omega_0 t)} f(t - n_0 \cdot y) \quad \text{for} \ t \in \mathbb{R} \ \text{and} \ y \in Q := \mathbb{R}^2 \setminus W$$

(1)

Here the frequency $\omega_0 > 0$ and the wave vector $k_0 \in \mathbb{R}^2$, $\omega_0 = |k_0|$ and $n_0 = k_0 / \omega_0$, $a \cdot b$ stands for the scalar product in $\mathbb{R}^2$. The profile $f \in C^\infty(\mathbb{R})$, and for some $\tau_0 > 0$

$$f(s) = \begin{cases} 
0, & s \leq 0 \\
1, & s \geq \tau_0 
\end{cases}$$

(2)

Denote

$$n_0 = (\cos \alpha, \ \sin \alpha)$$

(3)

(see Figure 1).

We consider the case

$$\max(0, \phi - \pi/2) < \alpha < \min(\pi/2, \phi)$$

(4)

for example (see Figure 1). Physically, in this case the front of the incident wave $u_{in}$ is identically zero on the wedge $W$ at the moment $t=0$ and is reflected by both sides of the wedge for $t > 0$. Other cases can be considered similarly.

Remark 1.1

By symmetry, we can assume $0 < \alpha < \phi/2$, hence $0 < \alpha < \pi/2$.

We consider the following wave problem in $Q$ with the Dirichlet boundary conditions:

$$\begin{cases}
\Box u(y, t) = 0, & y \in Q \\
u(y, t) = 0, & y \in \partial Q
\end{cases} \quad t \in \mathbb{R} \tag{5}$$

where $\Box = \partial_t^2 - \Delta$. We will state the result also for the case of the Neumann boundary conditions. We include the incident wave $u_{in}$ in the statement of the problem through the initial condition

$$u(y, t) = u_{in}(y, t), \quad y \in Q, \quad t < 0 \tag{6}$$

It is possible since $u_{in}(y, t)$ is a solution to problem (5) for $t < 0$: the boundary conditions in (5) hold for $t < 0$ since $u_{in}$ is then identically zero in a neighbourhood of $\partial Q$. Equivalently, $u(y, t)$ is the solution of the Cauchy problem for system (5) with the initial conditions

$$\begin{cases}
u(0, y) = u_{in}(0, y) \\
u(0, y) = \dot{u}_{in}(0, y)
\end{cases} \quad y \in Q \tag{7}$$

Let us denote the scattered and diffracted waves by

$$u_s(y, t) := u(y, t) - u_{in}(y, t), \quad u_d(y, t) := u_b(y, t) - u_s(y, t) \tag{8}$$

The reflected wave $u_r(y, t)$ is given by

$$u_r(y, t) := \begin{cases}
u_{r, 1}(\rho, \theta, t), & \phi \leq \theta \leq \theta_1 \\
0, & \theta_1 < \theta < \theta_2 \\
u_{r, 2}(\rho, \theta, t), & \theta_2 \leq \theta \leq 2\pi
\end{cases} \tag{9}$$

where $y = \rho e^{i\theta}$,

$$\theta_1 := 2\phi - \alpha, \quad \theta_2 = 2\pi - \alpha \tag{10}$$
(see Figure 1), and

\[ u_{r,1}(\rho, \theta, t) = -e^{i(k_1 \cdot y - \omega_0 t)} f(t - n_1 \cdot y), \quad u_{r,2}(\rho, \theta, t) = -e^{i(k_2 \cdot y - \omega_0 t)} f(t - n_2 \cdot y) \]

\[ k_1 = \omega_0 n_1, \quad n_1 = (\cos \theta_1, \sin \theta_1), \quad k_2 = \omega_0 n_2, \quad n_2 = (\cos \theta_2, \sin \theta_2) \]  

(11)

(cf. with \( n_0 \) in (3)).

In the present paper, we prove the existence of the nonstationary problem (5), (6) in the functional space \( E_{\epsilon,N} \). We will prove that this solution (total field \( u \)) is represented as the sum of the incident wave \( u_{in} \), reflected wave \( u_r \) and the diffracted wave \( u_d \). We find the Sommerfeld–Malyuzhinets-type representation for the diffracted wave \( u_d \). This representation allows us to prove that the total field \( u \) belongs to an appropriate functional class. We use the representation for the proof the Limiting Amplitude principle. The comments on previous works in the directions can be found in Reference [1].

The plan of our paper is the following. In Section 2, we give the main definitions and formulate the main result. In Section 3, we reduce the problem to the stationary one. In Sections 4 and 5, we describe some important properties of the Sommerfeld–Malyuzhinets-type integrals. In Section 6, we solve the stationary diffraction problem with parameter. In Sections 7–9, we prove the estimates for densities of the stationary diffracted wave. In Section 10, we solve the nonstationary scattering problem.

In Section 11, we give a Sommerfeld–Malyuzhinets-type explicit expression for the diffracted wave. In Sections 12–14, we prove that the obtained solution belongs to the functional space \( E_{\epsilon,N} \) and we find the exact values of \( \epsilon \) and \( N \). In Section 15, we prove the Limiting Amplitude principle.

In the appendix, we collect well known estimates of the Cauchy-type oscillatory integrals.

2. NOTATIONS AND MAIN RESULT

2.1. Notations

1. Let us denote \( C^+ := \{ \omega \in \mathbb{C} : \Im \omega > 0 \} \). Let us consider a function \( u(y, t) \in C(\mathbb{R}^+ \times \overline{Q}) \) s.t. \( |u(y, t)| \leq C(1 + |t|)^N \) for some \( C, N \) and \( u(y, t) = 0, \quad t < T(y) \). (Note that \( T(y) = n_0 \cdot y \) by (1), (2) for \( u = u_{in} \).) Define the Fourier–Laplace transform

\[ \hat{u}(y, \omega) := F_{t \to \omega}[u](\omega) := \int_{-\infty}^{\infty} e^{i \omega t} u(x, t) \, dt, \quad \Im \omega > 0 \]

Obviously, \( \hat{u}(y, \omega) \) is an analytic function in \( \omega \in \mathbb{C}^+ \) for each \( y \in \overline{Q} \).

2. We denote

\[ \hat{g}(\omega) := \hat{f}(\omega - \omega_0) = \int_0^\infty e^{i(\omega - \omega_0)s} f(s) \, ds \]  

(12)

Since \( f(s) \) satisfies (2), we have \( f'(s) \in C_0^\infty(\mathbb{R}), \supp f' \subset [0, \tau_0] \) and

\[ \hat{g}(\omega) = \frac{g_1(\omega)}{\omega - \omega_0}, \quad \omega \in \mathbb{C}^+ \]  

(13)
where
\[
\hat{g}_1(\omega) = i\hat{h}(\omega - \omega_0), \quad \omega \in \mathbb{C}
\]  
with \(h(s) := f'(s)\).

**Definition 2.1**
For an open set \(V \subset \mathbb{C}^n\) we denote by \(H(V)\) the set of analytic functions in \(V\).

By the Paley–Wiener theorem
\[
\hat{g}_1 \in H(\mathbb{C})
\]  
Moreover, \(\hat{g} \in S(\mathbb{R})\), and for any \(k \in \mathbb{N}, \ N > 0\)
\[
|\hat{g}^{(k)}(\omega)| \leq C_{k,N}(1 + |\omega|)^{-N}, \quad \omega \in \mathbb{C}
\]  
Denote by \(g_1(t)\) the inverse Fourier–Laplace transform of the function \(\hat{g}_1(\omega)\). Then (14) implies that
\[
g_1(t) = ie^{-i\omega_0 t}f'(t), \quad t \in \mathbb{R}
\]  
and (2) implies that
\[
\text{supp } g_1 \subset [0, \tau_0]
\]  

3. Denote by \(\mathcal{C}\) the Sommerfeld-type contour
\[
\mathcal{C} = \mathcal{C}_1 \cup \mathcal{C}_2
\]  
where \(\mathcal{C}_1 = \{\beta_1 - i\pi/2 : \beta_1 \geq 1\} \cup \{1 + i\beta_2 : -5/2\pi \leq \beta_2 \leq -\pi/2\} \cup \{\beta_1 - 5/2\pi i : \beta_1 \geq 1\}\) and \(\mathcal{C}_2\) is the symmetric to \(\mathcal{C}_1\) with respect to \(-3\pi/2\) (see Figure 2). We choose the orientation of the contours \(\mathcal{C}_{1,2}\) counterclock wise.

Let us denote (see Reference [1])
\[
\hat{\Gamma}_1^- = \{w \in \mathbb{C} : \text{Im}(-i\omega \sinh w) = 0, \ 0 \in \hat{\Gamma}_1^-\}
\]  
It is easy to check that for \(\omega_2 > 0\)
\[
\hat{\Gamma}_1^- = \left\{w = (w_1 + iw_2) : w_{1,2} \in \mathbb{R}, \ w_2 = \arctan\left(\frac{\omega_1}{\omega_2} \tanh w_1\right)\right\}
\]  
with the gauge \(\arctan 0 = 0\). Also, we define the contours
\[
\gamma(v) \equiv \hat{\Gamma}_1^- + iv
\]  
for \(v \in \mathbb{R}\)

4. We denote by \(\hat{\mathcal{Q}} = \mathcal{Q}(0, \{y\}) := |y|/(1 + |y|), \ y \in \mathbb{R}^2 \) or \(y \in \mathbb{R}\). Let us fix some \(\epsilon \geq 0\) and \(N \geq 0\).
Definition 2.2

(i) $E_{\epsilon}$ is the space of functions $u(y) \in C(\bar{Q}) \cap C^1(\bar{Q})$ with finite norm
\[ |u|_{E_{\epsilon}} = \sup_{y \in Q} (|u(y)| + \{y\}^\epsilon |\nabla u(y)|) < \infty \]

(ii) $E_{\epsilon,N}$ is the space of functions $u(y,t) \in C(\bar{Q} \times \mathbb{R}^+)$, with $\nabla u(y,t) \in C(\bar{Q} \times \mathbb{R}^+)$ with finite norm
\[ ||u||_{E_{\epsilon,N}} := \sup_{t \geq 0} \sup_{y \in \bar{Q}} (|u(y,t)| + (1 + t)^{-N} \{y\}^\epsilon |\nabla_y u(y,t)|) < \infty \] (19)

Note that for $\epsilon < 1$ the functions $u \in E_{\epsilon}$ have the finite local energy
\[ \int_{|y| < R} (|\nabla u(y)|^2 + |u(y)|^2) \, dy < \infty, \quad R > 0 \]

Remark 2.3

Obviously, if $u(y,t) \in E_{\epsilon,N}$, then $\hat{u}(y,\omega) \in E_{\epsilon}$ for $\omega \in \mathbb{C}^+$. 

5. We introduce the Sommerfeld–Malyuzhinets integral kernel:
\[ H(\beta) = H(\beta, \alpha, \Phi) := \coth(q(\beta + \pi i/2 - i\alpha)) - \coth(q(\beta - 3\pi i/2 + i\alpha)), \quad \beta \in \mathbb{C} \] (20)
where
\[ q := \frac{\pi}{2\Phi}, \quad \Phi := 2\pi - \phi \] (21)

For \( \omega \in \mathbb{C}^+ \) let us denote by \( \mathcal{S}(\rho, \theta, \omega) \) the Sommerfeld–Malyuzhinets-type integral
\[ \mathcal{S}(\rho, \theta, \omega) := \frac{i}{4\Phi} \int e^{-\omega \rho \sinh \beta} H(\beta + i\theta) \, d\beta, \quad \rho \geq 0, \quad \phi \leq \theta \leq 2\pi \] (22)

which absolutely converges (see Section 4).

2.2. The main result

We have proved in Reference [1] the uniqueness of solution \( u(y, t) \in \mathcal{E}_{\epsilon, N} \) of problem (5), (6), with \( 0 < \epsilon < 1 \) and \( N > 0 \). Namely we proved that the solution (if exists) is given by
\[ u(y, t) = F^{-1} \left[ \hat{u}(\rho, \theta, \omega) \right], \quad \rho > 0, \quad \phi < \theta \leq 2\pi \] (23)
in the polar coordinates \( y = \rho e^{i\theta} \), where
\[ \hat{u}(\rho, \theta, \omega) = \hat{g}(\omega) \mathcal{S}(\rho, \theta, \omega), \quad \omega \in \mathbb{C}^+ \] (24)

Now let us define the limiting amplitude \( A(\rho, \theta) \) by
\[ A(\rho, \theta) := \frac{i}{4\Phi} \int e^{-\omega \rho \sinh \beta} H(\beta + i\theta) \, d\beta \] (25)

The main result of this paper is the following.

**Theorem 2.4**

(i) Let the incident wave profile \( f(s) \) be a smooth function (see (2)). Then the function \( u(y, t) \), defined by (23), belongs to the space \( C^\infty(\overline{\Omega} \times \mathbb{R}) \cap \mathcal{E}_{\epsilon, N} \) with \( \epsilon = N = 1 - (\pi/\Phi) \), and is a solution to the scattering problem (5), (6).

(ii) The Limiting Amplitude principle holds: for any \( \rho_0 > 0 \)
\[ u(\rho, \theta, t) - e^{-i\omega t} A(\rho, \theta) \to 0, \quad t \to \infty \] (26)
uniformly for \( \rho \in [0, \rho_0] \) and \( \theta \in [\phi, 2\pi] \).

**Remark 2.5**

Similar results hold for the problem of type (5) with the Neumann boundary value conditions. Proofs for this alternative problem can be done by the same methods. In this case the density \( H(\beta) \) in expression (22) is replaced by
\[ H(\beta) = H_n(\beta, \pi, \Phi) := \coth(q(\beta + \pi i/2 - i\xi)) + \coth(q(\beta - 3\pi i/2 + i\xi)), \quad \beta \in \mathbb{C} \]

In this case, integral (22) absolutely converges for \( \phi < \theta < 2\pi \).
3. FOURIER–LAPLACE TRANSFORM

Here we recall some notations from Reference [1]. Let us consider a solution \( u(y, t) \) to problem (5), (6). We apply the Fourier–Laplace transform to Equation (5) and get the Helmholtz stationary equation with a parameter. First, we reduce the problem to the zero initial conditions to get the homogeneous Helmholtz equation. Namely, define the scattered wave by

\[
\begin{align*}
    u_s(y, t) &:= u(y, t) - u_{in}(y, t), \quad y \in Q, \quad t \in \mathbb{R} \\
    u_s(y, t) &\equiv 0, \quad y \in Q, \quad t \leq 0
\end{align*}
\]

where \( u(y, t) \) is a solution to problem (5), (6). Then (6) implies that

\[
\begin{align*}
    u_s(y, t) &\equiv 0, \quad y \in Q, \quad t \leq 0 \\
    u_s\big|_{\partial Q} &= - (u_{in})\big|_{\partial Q} \\
    \square u_s &= 0, \quad y \in Q
\end{align*}
\]

Furthermore, \( u_s(y, t) \) is a solution to the problem

\[
\begin{align*}
    \square u_s &= 0, \quad y \in Q \\
    u_s\big|_{\partial Q} &= - (u_{in})\big|_{\partial Q} \\
    t &\in \mathbb{R}
\end{align*}
\]

**Remark 3.1**

Let us note that \( u_{in}(y, t) \in \mathcal{E}_{0,0} \). Therefore, the condition \( u(y, t) \in \mathcal{E}_{e,N} \) is equivalent to \( u_s(y, t) \in \mathcal{E}_{e,N} \).

Hence, we get obviously from (28)

**Lemma 3.2**

The Fourier–Laplace transform \( \hat{u}_s(y, \omega, \cdot) \) is an analytic function in \( \omega \in \mathbb{C}^+ \) with values in \( \mathcal{E}_e \).

In particular, \( \hat{u}_s(y, \omega, \cdot) \) is a continuous function of \( (y, \omega) \in \overline{Q} \times \mathbb{C}^+ \). Let us apply the Fourier–Laplace transform in time to problem (29). First, we write the Fourier–Laplace transform of the function \( u_{in} \) given by (1):

\[
\hat{u}_{in}(y, \omega) = \hat{g}(\omega)e^{i\omega y_1 \cos \theta - x}
\]

Let us split \( \partial Q = Q_1 \cup Q_2 \) where \( Q_1 := \{ y = (y_1, y_2) \in \partial Q : y_2 = 0 \} \) and \( Q_2 := \{ y = (y_1, y_2) \in \partial Q : y_1 = \rho \cos \phi, y_2 = \rho \sin \phi \} \), \( \rho \geq 0 \). Note that \( Q_1 \) is given by \( \theta = 0 \) and \( y_1 = \rho \). Similarly, \( Q_2 \) is given by \( \theta = \phi = 2\pi - \Phi \) and \( y_2 = -\rho \sin \Phi \). Hence, the Dirichlet data of \( \hat{u}_{in}(\cdot, \omega) \) are equal to

\[
\begin{align*}
    \hat{u}_{in}(y, \omega) &= \hat{g}(\omega)e^{i\omega y_1 \cos \theta}, \quad y \in Q_1, \\
    \hat{u}_{in}(y, \omega) &= \hat{g}(\omega)e^{i\omega y_2 \cos(\theta + \Phi)/\sin \Phi}, \quad y \in Q_2
\end{align*}
\]

where \( \hat{g}(\omega) \) is defined by (12). Therefore the scattering problem (29) is reduced to the following stationary problem.
**Lemma 3.3**

Let \( u_s(y,t) \in \delta_{\epsilon,N} \) be a solution to problem (29) with \( \epsilon, N > 0 \). Then

(i) The function \( \hat{u}_s(y,\omega) \) is a solution to the boundary value problem with a parameter \( \omega \in \mathbb{C}^+ \),

\[
\begin{cases}
  (-\Delta - \omega^2)\hat{u}_s(y,\omega) = 0, & y \in \Omega \\
  \hat{u}_s(y,\omega) = -\hat{g}(\omega)e^{i\omega_1y\cos z}, & y \in \Omega_1 \\
  \hat{u}_s(y,\omega) = -\hat{g}(\omega)e^{-i\omega_2[\cos(\alpha+\Phi)/\sin \Phi]}, & y \in \Omega_2
\end{cases}
\]

(ii) The function \( \hat{u}_s(\cdot,\omega) \in E_{\epsilon} \) for \( \omega \in \mathbb{C}^+ \).

So, the nonstationary problem (29) is reduced to the stationary one, (31), with parameter \( \omega \in \mathbb{C}^+ \).

4. ON SOMMERFELD–M AlyuZHINets INTEGRALS

Let us examine the convergence of integral (22) and its derivatives in \( \omega \) and \( \rho, \theta \). First, let us prove the exponential decay of the function \( H \). The poles of the function \( H \) from (20) are given by

\[
\beta'_k = -i\pi/2 + i\alpha - 2i\Phi k, \quad \beta''_k = 3/2\pi i - i\alpha - 2i\Phi k, \quad k \in \mathbb{Z}
\]

For \( \delta > 0 \) denote \( C_\delta := \{ \beta \in \mathbb{C} : |\beta - \beta_k| \geq \delta, \forall k \in \mathbb{Z} \} \).

**Lemma 4.1**

For any \( \delta > 0 \) the estimate holds

\[
|H(\beta, z, \Phi)| \leq C_\delta e^{-\pi|\text{Re} \beta|}, \quad \beta \in C_\delta
\]

**Proof**

This follows from the representation of (29) in the form

\[
H(\beta, z, \Phi) = \frac{\sinh[iq(2\pi - z)]}{\sinh[q(\beta + i\pi/2 - i\alpha)] \sinh[q(\beta - 3/2\pi i + i\alpha)]}
\]

and (21). \( \square \)

Further, let us consider \( \omega := \omega_1 + i\omega_2 \) with \( \omega_1 \in \mathbb{R} \) and \( \omega_2 \geq 0 \) and \( \beta = \beta_1 + i\beta_2 \in \mathbb{C} \) with \( \beta_{1,2} \in \mathbb{R} \). Let us note that

\[
|e^{-\omega \rho \sinh \beta}| = e^{-\omega_1 \rho \sinh \beta_1 \cos \beta_2 + \omega_2 \rho \cosh \beta_1 \sin \beta_2}
\]

Hence, estimate (33) implies for every \( \delta > 0 \),

\[
|e^{-\omega \rho \sinh \beta} H(\beta + i\theta, z, \Phi)| \leq C_\delta e^{-\omega_1 \rho \sinh \beta_1 \cos \beta_2 + \omega_2 \rho \cosh \beta_1 \sin \beta_2 - (\pi/\Phi)|\beta_1|}, \quad \beta \in C_\delta
\]

**Denote** \( \Sigma := \mathbb{R}^+ \times \mathbb{R} \times \mathbb{C}^+ \).

---

Lemma 4.2

(i) Integral (22) converges absolutely and uniformly for \((\rho, \theta, \omega) \in \Sigma\), and can be rewritten as follows:

\[
\mathcal{S}(\rho, \theta, \omega) = \frac{i}{4\Phi} \int_{\mathcal{C}_+} e^{-\omega \rho \sinh \beta} H(\beta + i\theta, z, \Phi) \, d\beta, \quad \text{Re} \omega \geq 0 \tag{35}
\]

\[
\int_{\mathcal{C}_-} e^{-\omega \rho \sinh \beta} H(\beta + i\theta, z, \Phi) \, d\beta, \quad \text{Re} \omega \leq 0
\]

where \(\mathcal{C}_+ := (\mathcal{C}_1 + i\pi/4) \cup (\mathcal{C}_1 - 13\pi/4)\) and \(\mathcal{C}_- := (\mathcal{C}_1 - i\pi/4) \cup (\mathcal{C}_1 - 11\pi/4)\) (see Figure 3).

(ii) The function \(\mathcal{S}(\rho, \theta, \omega)\) is continuous in \(\Sigma\).

(iii) The function \(\mathcal{S}(\rho, \theta, \omega)\) is analytic in \(\omega \in \mathbb{C}^+\) and smooth in \((\rho, \theta) \in \bar{Q}\).

(iv) The function \(\mathcal{S}(\rho, \theta, \omega) \in C^\infty(\bar{Q} \times (\mathbb{R} \setminus \{0\}))\).

Proof

(i) For large \(\beta = \beta_1 + i\beta_2 \in \mathcal{C}\) we have either \(\beta = \beta_1 - \pi i/2\), or \(\beta = \beta_1 - 5\pi i/2\) with \(\beta_1 \in \mathbb{R}\). Then \(\beta_2 = -\pi/2\) or \(\beta_2 = -5\pi/2\), so \(\cos \beta_2 = 0\) and \(\sin \beta_2 = -1\). Therefore, estimate (34) implies that

\[
|e^{-\omega \rho \sinh \beta} H(\beta + i\theta, z, \Phi)| \leq C e^{-\omega_2 \rho \cosh \beta_1 - (\pi/\Phi) |\beta_1|}, \quad \beta \in \mathcal{C}, \quad \beta_1 \geq 1 \tag{36}
\]

Hence, for \(\omega_2, \rho \geq 0\) integral (22) converges absolutely and uniformly.
Let us prove (35), for example, for \( \omega_1 = \text{Re} \omega \geq 0 \). The regions of decay of the exponent (34) are shown by dash in Figures 2 and 3. Hence, by the Cauchy Residue theorem we can deform the contour \( \mathcal{C} \) to \( \mathcal{C}_+ \) in integral (22). Then we obtain
\[
\mathcal{S}(\rho, \theta, \omega) = \frac{i}{4 \Phi} \int_{\mathcal{C}_+} e^{-\rho \sinh \beta} H(\beta + i\theta, \omega, \Phi) d\beta, \quad \rho \geq 0, \quad \theta \in [\phi, 2\pi]
\]  
(37)

(ii) The continuity of the function \( \mathcal{S} \) follows by the Lebesgue Dominated Convergence theorem from estimate (36) and the continuity of the integrand in (22).

(iii) For \( \omega_2, \rho > 0 \) all the derivatives of integral (22) converge absolutely and uniformly by (36).

(iv) For example, let us consider \( \omega_1 = \text{Re} \omega > 0 \). Then \( \mathcal{S}(\rho, \theta, \omega) \) admits representation (37). Let \( \beta \in \mathcal{C}_1 + i\pi/4 \). For large \( \beta = \beta_1 + i\beta_2 \) we have either \( \beta = \beta_1 - \pi i/4 \), or \( \beta = \beta_1 - 9\pi i/4 \) with \( \beta_1 \in \mathbb{R} \). Then \( \beta_2 = -\pi/4 \) or \( \beta_2 = -9\pi/4 \), so \( \cos \beta_2 = 1/\sqrt{2} \) and \( \sin \beta_2 = -1/\sqrt{2} \). Therefore, estimate (34) implies that
\[
|e^{-\rho \sinh \beta} H(\beta + i\theta, \omega, \Phi)| \leq Ce^{-\omega_1 \rho \cosh \beta_1/\sqrt{1 - (\pi/\Phi)|\beta_1|}}, \quad \beta \in \mathcal{C}_1, \quad \beta_1 > 0
\]
since \( \omega_2 \geq 0, \rho > 0 \). Similarly, the same estimate holds for \( \beta \in -\mathcal{C}_1 - 13\pi/4 \). Hence, the formal derivatives of integral (37) with respect to \( \omega, \rho, \theta \) converge absolutely and uniformly. \( \square \)

5. STATIONARY PROBLEM

Let us consider the function \( \hat{u}(\rho, \theta, \omega) \) defined by (24).

Lemma 5.1

For \( \omega \in \mathbb{C}^+ \), the function \( \hat{u}(\cdot, \omega) \in C^\infty(\tilde{\Omega}) \) is a classical solution to the stationary problem
\[
\begin{align*}
(-\Delta - \omega^2)\hat{u}(y, \omega) &= 0, & y &\in \tilde{\Omega} \\
\hat{u}(\cdot, \omega)|_{\partial \tilde{\Omega}} &= 0
\end{align*}
\]  
(38)

Proof

First we note that \( \hat{u}(\cdot, \omega) \in C^\infty(\tilde{\Omega}) \) for \( \omega \in \mathbb{C}^+ \) by Lemma 4.2(iii) and (24).

The Helmholtz equation in (38) follows by the differentiation of the Sommerfeld integral (22) after the change of variable \( \beta \to \beta' - i\theta \) since \( (\Delta + \omega^2)e^{-\exp \sinh (\beta - i\theta)} = 0 \).

It remains to check that \( \hat{u} \) satisfies the boundary conditions in (38). Substitute \( \theta = \phi \) and \( 2\pi \) in (22), and use obvious identities
\[
H(\beta + i\phi) = H(-\beta - 3i\pi + i\phi), \quad H(\beta + 2\pi i) = H(-\beta - i\phi)
\]
Then the boundary conditions in (38) follow from the central symmetry of the contour \( \mathcal{C} \) with respect to the point \(-3\pi/2\). \( \square \)

Let us define
\[
\hat{u}_i(\rho, \theta, \omega) = \hat{u}(\rho, \theta, \omega) - \hat{u}_m(\rho, \theta, \omega)
\]  
(39)

similarly to (27).
Corollary 5.2
For $\omega \in \mathbb{C}^+$, the function
\[
\hat{u}_s(\cdot, \cdot, \omega) \in C^\infty(\overline{\Omega})
\]
and is a classical solution to the stationary problem (31).

Proof
The function $-u_{in}(\rho, \theta, \omega) = -\hat{g}(\omega)e^{i\rho \cos(\theta-x)} \in C^\infty(\overline{\Omega})$ and is a solution of problem (31) for $\omega \in \mathbb{C}^+$. Therefore, the corollary follows from Lemma 5.1.

6. INCIDENT, REFLECTED AND DIFFRACTED WAVE

In Sections 7–14, we prove the statement (i) of Theorem 2.4 for the function $u(y,t)$ defined by (23): the function is a solution to problem (5), (6) and belongs to $\mathcal{E}_{\epsilon,N}$ with $\epsilon,N$ defined in Theorem 2.4. We will prove that $u(\rho,\theta,t)$ is a smooth function and satisfies (5), (6) in the classical sense (see Corollary 10.3). The inclusion will be proved in Sections 11–14.

We will deduce (6) from (28) by the Paley–Wiener theorem, using the estimates of $\hat{u}_s(\rho,\theta,\omega)$ for $\omega \in \mathbb{C}^+$. Note that $\mathcal{S}(\rho,\theta,\omega)$ and $\hat{u}(\rho,\omega,\theta) = \hat{u}_d(\rho,\omega,\theta) + \hat{u}_{in}(\rho,\omega,\theta)$ are not bounded for $\omega \in \mathbb{C}^+$ since $u_{in}(x,t) \neq 0$ for $t < 0$. Therefore, we have to extract first the incident wave from integral (22).

The contour $\mathcal{C}$ in integral (22) crosses 'bad zones' between $\gamma(-\pi)$ and $\gamma(-2\pi)$, where $\Re(\omega \sinh \beta) < 0$, and the exponent $e^{-\omega \sinh \beta}$ is growing for $\Im \omega \to +\infty$. We will see that this growing part of the integral just corresponds to the incident wave.

To extract the incident wave, we will split the function $\mathcal{S}(\rho,\theta,\omega)$, in (24), into three summands

\[
\mathcal{S} = \mathcal{S}_{in} + \mathcal{S}_r + \mathcal{S}_d
\]

Namely, let us define the functions

\[
\begin{cases}
\mathcal{S}_d(\rho,\theta,\omega) := \frac{i}{4\phi} \int_{\mathcal{C}_0} e^{-\omega p \sinh \beta} H(\beta + i\phi, \alpha, \Phi) d\beta, & \theta \neq \theta_1, \\
\mathcal{S}_{in}(\rho,\theta,\omega) := e^{i\rho \cos(\theta-x)} & \omega \in \mathbb{C}^+ \\
\mathcal{S}_r(\rho,\theta,\omega) := \begin{cases} -e^{i\rho \cos(\theta-\theta_2)}, & \phi \leq \theta \leq \theta_1 \\
0, & \theta_1 < \theta < \theta_2 \\
-e^{i\rho \cos(\theta-\theta_2)}, & \theta_2 \leq \theta \leq 2\pi \end{cases}
\end{cases}
\]

From the definition of the contour $\mathcal{C}_0$ and estimate (33) it follows that the integral in (41) converges absolutely for $\omega \in \mathbb{C}^+$ and defines a continuous function of $\omega \in \mathbb{C}^+$.

Let us note that

\[
\hat{u}_{in}(y,\omega) = \hat{g}(\omega)\mathcal{S}_{in}(\rho,\theta,\omega)
\]
by (30). Similarly, calculating the Fourier–Laplace transform of \( u_t(\rho, \theta, t) \), defined by (9), we obtain

\[
\hat{u}_t(y, \omega) = \begin{cases} 
\hat{u}_{t,1}(\rho, \theta, \omega), & \phi \leq \theta \leq \theta_1 \\
0, & \theta_1 < \theta < \theta_2 \\
\hat{u}_{t,2}(\rho, \theta, \omega), & \theta_2 \leq \theta \leq 2\pi 
\end{cases}
\]

where

\[
\hat{u}_{t,1}(\rho, \theta, \omega) = -e^{iy\rho \cos(\theta - \phi)} \hat{g}(\omega), \quad \hat{u}_{t,2}(\rho, \theta, \omega) = -e^{iy\rho \cos(\theta - \phi)} \hat{g}(\omega) 
\] (43)

Therefore,

\[
\hat{u}_t(\rho, \theta, \omega) = \hat{g}(\omega) S_r(\rho, \theta, \omega) 
\] (44)

**Remark 6.1**

Let (40) hold. Then (39), (24) and (42) imply that

\[
\hat{u}_s = \hat{u} - \hat{u}_{in} = \hat{g}(S_r - S_{in}) = \hat{g} S_s 
\] (45)

where

\[
S_s := S_r - S_{in} = S_r + S_d 
\] (46)

Hence, (8) and (44) imply that

\[
\hat{u}_d = \hat{u}_s - \hat{u}_r = \hat{g}(S_r + S_d - S_r) = \hat{g} S_d 
\]

We will call \( S_r, S_d, S_{in}, S_t, S_s \) as densities of the total, diffracted, incident, reflected and diffracted waves, respectively. The incident part \( S_{in}(\rho, \theta, \cdot) \) is unbounded in \( C^+ \) while \( S_t(\rho, \theta, \cdot) \) and \( S_d(\rho, \theta, \cdot) \) are bounded in \( C^+ \) as we will check in Sections 8 and 9. Hence, \( \hat{u}_s(\rho, \theta, \cdot) \) is bounded in \( C^+ \).

### 7. PROOF OF THE SPLITTING

To prove splitting (40), we will deform the contour of integration \( \mathcal{C} \) in (22). Namely, define the contour

\[
\mathcal{C}_0 := \gamma_1 \cup \gamma_2, \quad \gamma_1 := \{\beta_1 - i\pi/2, \beta_1 \in \mathbb{R}\}, \quad \gamma_2 := \{\beta_1 - 5i\pi/2, \beta_1 \in \mathbb{R}\} 
\] (47)

We direct the contour \( \mathcal{C}_0 \) such that the strip between \( \gamma_1 \) and \( \gamma_2 \) remains from the left (see Figure 4).

We are going to deform the contour \( \mathcal{C} \) in (22) to the contour \( \mathcal{C}_0 \). Then the integral also changes and the difference is the sum of residues between \( \mathcal{C} \) and \( \mathcal{C}_0 \) by the Cauchy Residue theorem.

Let us determine the poles and residues. By (32), the poles of the function \( H(\beta + i\theta, \alpha, \Phi) \) as the function of \( \beta \) are

\[
\beta'_k(\theta) := -i\pi/2 + i\alpha - 2i\Phi k - i\theta, \quad \beta''_k(\theta) = 3i\pi/2 - i\alpha - 2i\Phi k - i\theta, \quad k \in \mathbb{Z}
\]

We have to take into account the poles between \( \gamma_1 \) and \( \gamma_2 \), i.e. \( \text{Im} \beta \in [-5\pi/2, -\pi/2] \).
The pole $\beta'_k(\theta)$ belongs to the interval $[-5\pi/2, -i\pi/2]$ only for $k = 0$ since $\theta \in [\phi, 2\pi]$. So,

$$\beta'_0(\theta) := -i\frac{\pi}{2} + ix - i\theta \in [-5\pi/2 + ix; -i\pi/2 + ix - i\phi], \quad \theta \in [\phi, 2\pi]$$

(48)

By (4), we get from (48) that

$$\beta'_0(\theta) \in [-5\pi/2; -i\pi/2], \quad \theta \in [\phi, 2\pi]$$

(49)

As we will see further, the residue in this pole corresponds to the incident wave $u_{in}$.

Similarly, the pole $\beta''_k(\theta)$ $\in [-5\pi/2, -i\pi/2]$ only for $k = 0$ and 1. For $k = 0$

$$\beta''_0(\theta) = 3i\pi/2 - ix - i\theta \in [-i\pi/2 - ix, -i\pi/2], \quad \theta_2 \leq \theta \leq 2\pi$$

where $\theta_2$ is defined in (10). Then Remark 1.1 implies that

$$\begin{cases}
\beta''_0(\theta) \in [-5\pi/2; -i\pi/2), \quad \theta \in [\theta_2; 2\pi] \\
\beta''_0(\theta_2) = -i\pi/2
\end{cases}$$

As we will see further the residue in this pole corresponds to the reflected wave from the face $\theta = 2\pi$ of the angle. For $k = 1$

$$\beta''_1(\theta) = -5i\pi/2 + 2i\phi - ix - i\theta \in [-5i\pi/2 + i\phi - ix, -i\pi/2], \quad \phi \leq \theta \leq \theta_1$$
where $\theta_1$ is defined in (10). Then Remark 1.1 implies that
\[
\begin{align*}
\beta''_1(\theta) &\in (-5i\pi/2; -i\pi/2], \quad \theta \in [\phi, \theta_1) \\
\beta''_1(\theta_1) &= -5i\pi/2
\end{align*}
\] (50)
As we will see further, this pole corresponds to the wave reflected from the face $\theta = \phi$.

**Definition 7.1**

Critical directions correspond to the angles $\theta_2$ and $\theta_1$ defined by (10). Critical rays $l_1$, $l_2$ are the rays in $Q$, corresponding to the critical direction.

Estimate (33) implies that
\[
[e^{-\omega \sinh \beta}H(\beta + i\theta, \alpha, \Phi)] \leq C(\theta)e^{-(\pi/\Phi)|\text{Re} \beta|}, \quad \omega \in \mathbb{R}, \quad \beta \in \mathcal{C}_0, \quad \theta \in [\phi, 2\pi], \quad \theta \neq \theta_{1,2}
\]
Thus integral (41) converges for $\theta \neq \theta_1, \theta_2$, and diverges for $\theta = \theta_1, \theta_2$ since the integrand has the poles on the contour of integration $\mathcal{C}_0$ then. Hence, the integral is a discontinuous function at $\theta = \theta_1$ and $\theta_2$.

**Lemma 7.2**

(i) Splitting (40) holds,
\[
\mathcal{F}(\rho, \theta, \omega) = \mathcal{F}_\text{in}(\rho, \theta, \omega) + \mathcal{F}_\text{r}(\rho, \theta, \omega) + \mathcal{F}_\text{d}(\rho, \theta, \omega)
\] (51)
(ii) For $(\rho, \theta) \in \overline{Q}$ with $\theta \neq \theta_{1,2}$ we have
\[
\mathcal{F}_\text{d}(\rho, \theta, \omega) \in H(C^+), \quad \mathcal{F}_\text{d}(\rho, \theta, \omega) \in C^\infty((\overline{Q}\setminus\{l_1 \cup l_2\}) \times (\mathbb{R}\setminus 0))
\] (52)

**Proof**

Let us deform the contour $\mathcal{C}$ to the contour $\mathcal{C}_0$ in integral (22). Using (49), (50) and first formula from (41), we obtain by the Cauchy Residue theorem, that
\[
\mathcal{F}(\rho, \theta, \omega) = \mathcal{F}_\text{d}(\rho, \theta, \omega)
\]
\[
\begin{align*}
&+ \left\{ \frac{\pi}{2\Phi} \text{res}_{\beta = \beta_0'(\theta)} e^{-\omega \sinh \beta}H(\beta + i\theta, \alpha, \Phi) \right. \\
&\quad \times e^{-\omega \sinh \beta}H(\beta + i\theta, \alpha, \Phi), \quad \phi \leq \theta \leq \theta_1
\cr
&+ \frac{\pi}{2\Phi} \text{res}_{\beta = \beta_0'(\theta)} e^{-\omega \sinh \beta}H(\beta + i\theta, \alpha, \Phi), \quad \theta_1 \leq \theta \leq 2\pi
\cr
&+ \frac{\pi}{2\Phi} \text{res}_{\beta = \beta_0'(\theta)} e^{-\omega \sinh \beta}H(\beta + i\theta, \alpha, \Phi) + \frac{\pi}{2\Phi} \text{res}_{\beta = \beta_0'(\theta)} \\
&\quad \times e^{-\omega \sinh \beta}H(\beta + i\theta, \alpha, \Phi), \quad \theta_2 \leq \theta \leq 2\pi
\end{align*}
\]
Calculating the residues, we obtain (51). Statement (52) follows from (51), Lemma 4.2(iii), (iv), and expressions (41) for $S_{\text{in}}$ and $S_{\text{r}}$. The lemma is proved.

**Remark 7.3**

The proof shows that the incident wave corresponds to the residue at $\beta = \beta_0'(\theta)$, and the reflected one to the residues at $\beta = \beta_0''(\theta), \beta''_r(\theta)$.
8. DENSITY OF THE DIFFRACTED WAVE

Remind that one of our aims is to prove (28). We will deduce it by the Paley–Wiener theorem using the estimates for the density \( \mathcal{S}_s \) of the diffracted wave (46). It suffices to estimate the density of the diffracted wave \( \mathcal{S}_d \) that we prove in this section.

Let us note that the reflected density \( \mathcal{S}_r \) is obviously discontinuous at the critical directions \( \theta = \theta_1 \) and \( \theta_2 \), while the incident density \( \mathcal{S}_i \) and the total density \( \mathcal{S} \) are smooth everywhere. Therefore, the diffracted density \( \mathcal{S}_d = \mathcal{S} - \mathcal{S}_r - \mathcal{S}_i \) also is discontinuous at \( \theta = \theta_1 \) and \( \theta_2 \).

**Theorem 8.1**
The density \( \mathcal{S}_d \) satisfies the following estimates:

\[
|\mathcal{S}_d(\rho, \theta, \omega)| \leq C, \quad \omega \in \mathbb{C}^+, \quad \rho \geq 0, \quad \theta \in [\phi, 2\pi], \quad \theta \neq \theta_{1,2}
\]  
(53)

**Proof**
The contour \( \mathcal{C}_0 \) in integral (41) consists of two parts \( \gamma_1 \) and \( \gamma_2 \). Hence it suffices to prove that the function

\[
M_1(\rho, \theta, \omega) := \frac{i}{4\Phi} \int_{\gamma_1} e^{-i\rho \sinh \beta} H(\beta + i\theta) \, d\beta
\]  
(54)

satisfies estimate (53), since the function

\[
M_2(\rho, \theta, \omega) := \frac{i}{4\Phi} \int_{\gamma_2} e^{-i\rho \sinh \beta} H(\beta + i\theta) \, d\beta
\]

can be bounded similarly. We will omit below the indices \( x, \Phi \) in the expression for \( H \).

So, we consider the function \( M_1 \). For \( \beta \in \gamma_1 \) we have \( \beta := -i\pi/2 + \beta_1 \) where \( \beta_1 \in \mathbb{R} \). Substituting this expression in integral (54), and changing \( \beta_1 \) by \( \beta \), we obtain

\[
M_1(\rho, \theta, \omega) := -\frac{i}{4\Phi} \int_{\mathbb{R}} e^{i\rho \cosh \beta} H(-i\pi/2 + \beta + i\theta) \, d\beta
\]

Inequality (33) implies that the integral is bounded if the function \( \beta \mapsto H(-i\pi/2 + \beta + i\theta) \) does not have any poles in \( \beta \in \mathbb{R} \) for \( \theta \in [\phi, 2\pi] \). In particular, this estimate holds for \( \theta \) such that \( |\theta - \theta_k| \geq \delta, \, k = 1, 2 \). On the other hand, the function \( H \) has a pole \( \beta = 0 \) when \( \theta = \theta_2 \). Then the estimate depends on the derivative of the integrand. The differentiation gives the factor \( i\rho \) and we do not obtain the uniform estimate of type (53). Therefore we need more delicate methods. We use the method of the steepest descent [14,15]. Namely, we represent the function \( M_1 \) in the following form:

\[
M_1(\rho, \theta, \omega) := M_3(\rho, \theta, \omega) + M_4(\rho, \theta, \omega)
\]

where

\[
M_3(\rho, \theta, \omega) := \int_{|\beta| < 1} e^{i\rho \cosh \beta} H(-i\pi/2 + \beta + i\theta) \, d\beta
\]

and

\[
M_4(\rho, \theta, \omega) := \int_{|\beta| > 1} e^{i\rho \cosh \beta} H(-i\pi/2 + \beta + i\theta) \, d\beta
\]
The function $M_4$ satisfies an estimate of type (53) by (33) since

$$|e^{i\omega \rho \cosh \beta}| \leq e^{-\omega_2 \rho}, \quad \beta \in \mathbb{R}, \quad \omega = \omega_1 + i\omega_2, \quad \omega_2 \geq 0$$

It remains to prove an estimate of type (53) for the function $M_3$. Representation (20) gives

$$H(-i\pi/2 + \beta + i\theta) = \coth q(\beta + i\theta - i\zeta) - \coth q(-2i\pi + \beta + i\theta + i\zeta), \quad \beta \in \mathbb{R}$$

By (4) the function $\coth q(\beta + i\theta - i\zeta)$ is analytic for $\beta \in [-1, 1]$. Finally, it suffices to prove estimate (53) for the function

$$M_5(\rho, \omega, \omega_2) := \int_{|\beta| \leq 1} e^{i\omega \rho \cosh \beta} \coth q(-2i\pi + \beta + i\theta + i\zeta) d\beta$$

The integrand has a pole in the point $\beta = 0$ for $\theta = \theta_2$ (see (10)). Let us consider $\theta = \theta_2 + \varepsilon$, $|\varepsilon| \leq \varepsilon_0$, where $\varepsilon_0 > 0$ is sufficiently small. Then we can rewrite the function $M_5$ as the function of $\rho, \varepsilon, \omega$:

$$M_6(\rho, \varepsilon, \omega, \omega_2) := M_5(\rho, \theta_2 + \varepsilon, \omega) = \int_{|\beta| \leq 1} e^{i\omega \rho \cosh \beta} \coth q(\beta + i\varepsilon) d\beta$$

First, we represent $M_6$ in the following form:

$$M_6(\rho, \varepsilon, \omega, \omega_2) := \int_{|\beta| \leq 1} e^{i\omega \rho \cosh \beta}(e^{-\omega_2 \rho \cosh \beta} - e^{-\omega_2 \rho}) \coth q(\beta + i\varepsilon) d\beta$$

$$+ e^{-\omega_2 \rho} \int_{|\beta| \leq 1} e^{i\omega \rho \cosh \beta} \coth q(\beta + i\varepsilon) d\beta, \quad \omega_1 \in \mathbb{R}, \quad \omega_2 \geq 0, \quad \rho \geq 0$$

Note that

$$|(e^{-\omega_2 \rho \cosh \beta} - e^{-\omega_2 \rho}) \coth q(\beta + i\varepsilon)| \leq C(\varepsilon_0), \quad \omega_2 \geq 0, \quad \beta \in [-1, 1]$$

for $|\varepsilon| < \varepsilon_0$. Therefore, it suffices to prove an estimate of type (53) for the function

$$M_7(\rho, \varepsilon, \omega) := \int_{|\beta| \leq 1} e^{i\omega \rho \cosh \beta} \coth q(\beta + i\varepsilon) d\beta, \quad \omega \in \mathbb{R}, \quad \rho \geq 0$$

(55)

Since $\coth q(\beta + i\varepsilon) \sim 1/q(\beta + i\varepsilon)$ for $|\beta| \leq 1$, estimate (53) for $M_7$ follows from Proposition A.1(ii) of the appendix.

9. DERIVATIVES OF THE DENSITY OF DIFRACTED WAVE

To prove Theorem 2.4(i) it is necessary to prove, in particular that $u(y, t) \in C^\infty(\mathring{Q} \times \mathbb{R})$. We will prove the smoothness in Section 10, using the estimates for derivatives of the density $\mathcal{S}_n$ of the scattered wave. The estimates will be proved in the present section. Note that the estimates do not follow directly from representations (23), (24) since the function $\mathcal{S}(\rho, \theta, \omega)$ is growing exponentially in $\omega \in \mathbb{C}^+$. The growth is related to the density $\mathcal{S}_n$ of the incident wave in (41). So, to bound the derivatives, we extract the incident wave as above. We also extract the reflected wave since the estimates for its derivatives are obvious.
The following theorem will be proved similarly to Theorem 8.1. Let us denote by \( \mathbb{N}_0 := \mathbb{N} \cup \{0\} \).

**Theorem 9.1**
The density of the diffracted wave \( \mathcal{S}_d \) has all derivatives and the estimates hold

\[
\left| \frac{\partial^2}{\partial \rho^2 \partial \theta^2} \mathcal{S}_d(\rho, \theta, \omega) \right| \leq C(\delta, x)(1 + |\omega|)^{\varepsilon_1} \rho^{\varepsilon_1}, \quad \omega \in \mathbb{C}^+ \setminus \{0\}
\]

\[
\rho \geq \delta > 0, \quad \theta \in [\phi, 2\pi], \quad \theta \neq \theta_{1,2}, \quad C(\delta, x) > 0
\]

(56)

for \( x := (x_1, x_2) \in \mathbb{N}_0 \times \mathbb{N}_0, \quad |x| \geq 0 \).

**Proof**

I. The estimates for the case \(|x| = 0\) are proved in the previous section. First, we prove that derivatives (56) exist for \( x \neq 0 \) and find an appropriate expression for them. In contrast to the case \( x = 0 \), the integrals which express the derivatives, do not converge absolutely on the contour \( C_0 \) for \( \omega \in \mathbb{R} \). Therefore, we have to modify the proof for the case \( x \neq 0 \).

Let us fix a function \( \kappa(\beta) \in C^\infty(\mathbb{R}) \) such that

\[
\kappa(\beta) := \begin{cases} 
0, & \beta \leq 1 \\
n/4, & \beta \geq 2
\end{cases}
\]

Let \( \mathcal{B}_\pm \) be the contours in \( \mathbb{C} : \mathcal{B}_+ := \{\beta_1 \pm i\kappa(\beta_1) - i\pi/2, \pm \beta_1 \geq 0\}; \quad \mathcal{B}_- := \{\beta_1 \mp i\kappa(\beta_1) - i\pi/2, \pm \beta_1 \geq 0\} \). We direct the contour \( \mathcal{B}_+ \) similarly to \( \gamma_1 \) and the contour \( \mathcal{B}_- - 2\pi i \) similarly to \( \gamma_2 \) (see Figure 5).

Then we obtain the modified representation for \( \mathcal{S}_d \):

\[
\mathcal{S}_d(\rho, \theta, \omega) = \frac{i}{4\Phi} \int_{\mathcal{B}_+ \cup (\mathcal{B}_- - 2\pi i)} e^{-\omega \rho \sinh \beta} H(\beta + i\theta) \, d\beta
\]

\[
\omega \in \mathbb{C}^+, \quad \rho \geq 0, \quad \phi \leq \theta \leq 2\pi, \quad \theta \neq \theta_{1,2}
\]

(57)

by the definition of \( \mathcal{S}_d \) in (41), estimate (34), and the Cauchy theorem.

Here the sign ‘+’ is taken for \( \text{Re} \omega \geq 0 \), and the sign ‘−’ is taken for \( \text{Re} \omega < 0 \). Differentiating formally the integral with respect to \( \rho \), we obtain the absolutely convergent integral

\[
\frac{\partial^{\varepsilon_1}}{\partial \rho^{\varepsilon_1}} \mathcal{S}_d(\rho, \theta, \omega) = \frac{i}{4\Phi} (-\omega)^{\varepsilon_1} \int_{\mathcal{B}_+ \cup (\mathcal{B}_- - 2\pi i)} e^{-\omega \rho \sinh \beta} H(\beta + i\theta)(\sinh \beta)^{\varepsilon_1} \, d\beta
\]

(58)

where the contour \( \mathcal{B}_+ \cup (\mathcal{B}_- - 2\pi i) \) is chosen for \( \text{Re} \omega \geq 0 \) and the contour \( \mathcal{B}_- \cup (\mathcal{B}_- - 2\pi i) \) is chosen for \( \text{Re} \omega < 0 \).

The contour of integration \( \mathcal{B}_+ \cup (\mathcal{B}_+ - 2\pi i) \) lies in the shaded regions of the decay of the exponent if \( \text{Re} \omega, \text{Im} \omega \geq 0 \) and \( \omega \neq 0 \). Similarly, the contour of integration \( \mathcal{B}_- \cup (\mathcal{B}_- - 2\pi i) \) lies in the shaded regions of the decay of the exponent if \( \text{Re} \omega < 0 \) and \( \text{Im} \omega > 0 \). Therefore, integral (58) converges uniformly for \( \rho \geq \delta > 0, \quad \theta \in [0, 2\pi], \quad |\theta - \theta_{1,2}| \geq \nu > 0 \). Hence, the formal differentiation (58) is justified.
Figure 5. Contours $B_+, B_- - 2\pi i$. The case $\Re \omega \geq 0$.

Now we can calculate derivatives (56). Namely, differentiating formally (57), we get that

$$\frac{\partial^2}{\partial \rho^2 \partial \theta^2} \mathcal{L}_d(\rho, \theta, \omega) = \left( \frac{1}{4} \right)^2 i \frac{\omega}{4\Phi} (-\omega)^z \int_{\mathcal{B}_+ \cup (\mathcal{B}_+ - 2\pi i)} e^{-\omega \sinh \beta} \frac{\partial \mathcal{L}_d}{\partial \beta^z} \times [H(\beta + i\theta)(\sinh \beta)^y] d\beta$$

Integrating by parts, we obtain

$$\frac{\partial^2}{\partial \rho^2 \partial \theta^2} \mathcal{L}_d(\rho, \theta, \omega) = \frac{i^{z_2+1}}{4\Phi} (-\omega)^z \rho^{z_2} \int_{\mathcal{B}_+ \cup (\mathcal{B}_+ - 2\pi i)} e^{-\omega \sinh \beta} H(\beta + i\theta)
\times (\sinh \beta)^y (\cosh \beta)^{z_2} d\beta$$

(59)

II. Now let us prove the uniform estimate (56) using representation (59). First let us bound derivative (58) for $\Re \omega \geq 0$. The case $\Re \omega < 0$ is analysed similarly. We will prove that

$$\left| \int_{\mathcal{B}_+} e^{-\omega \sinh \beta} H(\beta + i\theta)(\sinh \beta)^y (\cosh \beta)^{z_2} d\beta \right|$$

$$\leq C(\delta, \alpha) \left( \frac{1 + |\omega|}{|\omega|} \right)^{|z| - (\pi, \Phi)}, \quad \rho \geq \delta, \quad \theta \in [\phi, 2\pi], \quad \theta \neq \theta_{1,2}, \quad C(\delta, \alpha) > 0$$

(60)

if $\Re \omega, \Im \omega \geq 0$ and $\omega \neq 0$.  

Copyright © 2006 John Wiley & Sons, Ltd.  

The same integral over the contour \( \mathcal{B}_+ - 2\pi i \) can be estimated similarly. These estimates provide (56) by (59).

To prove (60), let us split the integral into two summands:

\[
A_1(\rho, \theta, \omega) := \int_{\mathcal{B}_+ \cap \{ |\beta| \geq 2 \}} e^{-\rho \psi} \sinh \beta H(\beta + i\theta)(\sinh \beta)^{a_1}(\cosh \beta)^{a_2} \, d\beta
\]

and

\[
A_2(\rho, \theta, \omega) := \int_{\mathcal{B}_+ \cap \{ |\beta| \leq 2 \}} e^{-\rho \psi} \sinh \beta H(\beta + i\theta)(\sinh \beta)^{a_1}(\cosh \beta)^{a_2} \, d\beta
\]  \hspace{1cm} (61)

Let us note that the function \( A_2(\rho, \theta, \omega) \) is defined for \( \theta \neq \theta_{1,2} \), because the poles of \( H(\beta + i\theta) \) lie in imaginary axis for \( \theta \in [0, 2\pi] \).

Let us bound the integral

\[
A_1^+(\rho, \theta, \omega) := \int_{\mathcal{B}_+ \cap \{ |\beta| \geq 2 \}} e^{-\rho \psi} \sinh \beta H(\beta + i\theta)(\sinh \beta)^{a_1}(\cosh \beta)^{a_2} \, d\beta
\]

The corresponding integral over \( \mathcal{B}_+ \cap \{ \beta_1 \leq 2 \} \) can be bounded similarly. The definition of the contour \( \mathcal{B}_+ \) implies that

\[
A_1^+(\rho, \theta, \omega) := \left( \frac{\sqrt{2}}{2} \right)^{x_1+x_2} \int_2^\infty e^{-\rho \sqrt{2}/2}(\sinh \beta - i\cosh \beta) H(\beta - i\pi/4 + i\theta)
\]

\[\times (\sinh \beta - i\cosh \beta)^{a_1}(\cosh \beta - i\sinh \beta)^{a_2} \, d\beta\]

Hence, estimate (33) implies that

\[
|A_1^+(\rho, \theta, \omega)| \leq C_1 \int_2^\infty e^{a_1(\omega_1 \sinh \beta + \omega_2 \cosh \beta)} e^{(\rho\pi/4 - \theta)} \, d\beta
\]

\[\leq C_1 \int_2^\infty e^{-a_2(\omega_1 + \omega_2)\rho e^{\theta} e^{(\rho\pi/4 - \theta)}} \, d\beta
\]

for \( \omega := \omega_1 + i\omega_2 \), where \( a_1, a_2 > 0 \).

Changing the variable \( \xi := (\omega_1 + \omega_2)\rho e^{\theta} \) in this integral, and using (21) and the conditions \( \phi < \pi, \ |x| \geq 1, \) we get

\[
|A_1^+(\rho, \theta, \omega)| \leq C_1 \int_0^\infty e^{-a_2(\omega_1 + \omega_2)\rho e^{\theta} e^{(\rho\pi/4 - \theta)}} \, d\xi
\]

\[\leq C(\delta) e^{(\rho\pi/4 - \theta)} \leq \rho \geq \delta > 0
\]  \hspace{1cm} (62)

It remains to bound the function \( A_2 \) from (61). The integral over \( \mathcal{B}_+ \cap \{ 1 \leq |\beta| \leq 2 \} \) can be estimated using (34):

\[
\left| \int_{\mathcal{B}_+ \cap \{ 1 \leq |\beta| \leq 2 \}} e^{-\rho \psi} \sinh \beta H(\beta + i\theta)(\sinh \beta)^{a_1}(\cosh \beta)^{a_2} \, d\beta \right| \leq C, \quad \rho \geq 0, \ \theta \in [\phi, 2\pi]
\]  \hspace{1cm} (63)
Therefore, it remains to bound the integral
\[
A'_2(\rho, \theta, \omega) := \int_{B_+ \cap \{ |\beta| \leq 1 \}} e^{-i\omega \sin \beta} H(\beta + i\theta)(\sinh \beta)^{\gamma_1} (\cosh \beta)^{\gamma_2} \, d\beta
\]
Let us check the estimate of type (63) for this integral. If \( \theta \in [\phi, 2\pi] \) is not close to \( \theta'' \), or \( \gamma_2 > 0 \), estimate (63) for \( A'_2 \) is obvious, since the point \(-\pi i/2\) is not a pole of the function \( H(\beta + i\theta)(\cosh \beta)^{\gamma_2} \) by (33) and (4). If \( \theta \) is close to \( \theta'' \) and \( \gamma_2 = 0 \), the estimate of type (63) for this integral is reduced to the estimate of the function \( M_7 \) from (55).

Now estimate (60) follows from (62), and (63).

**Corollary 9.2**
Estimates (56) imply that
\[
|\nabla \mathcal{S}_d(\rho, \theta, \omega)| \leq C(\delta)(1 + |\omega|), \quad \omega \in \mathbb{C}^+ \setminus \{0\}, \quad \rho \geq \delta > 0, \quad \theta \in [\phi, 2\pi], \quad \theta \neq \theta_{1,2}
\]
for any \( \delta > 0 \).

**Corollary 9.3**
The density \( \mathcal{S}_s(\rho, \theta, \omega) \) of the scattered wave has all the derivatives with respect to \( \rho, \theta \) in the region \( \mathcal{O} \), and the estimates of type (56) hold for the derivatives. In particular, the estimates hold for \( \nabla \mathcal{S}_s \) in this region.

**Proof**
Equation (46), Lemma 4.2(iv), and the definition of \( \mathcal{S}_{in} \) in (41) imply that \( \mathcal{S}_s(\rho, \theta, \omega) \in C^\infty(\mathcal{O} \times (\mathbb{R} \setminus \{0\})) \). On the other side, representation (46) \( \mathcal{S}_s = \mathcal{S}_r + \mathcal{S}_d \), Theorem 9.1 and the definition of \( \mathcal{S}_r \) in (41) imply estimates (56) for \( \theta \neq \theta_{1,2} \). Hence, the estimates hold for \( \theta \in [\phi, 2\pi] \).

10. THE SCATTERED WAVE

In this section, we start to prove Theorem 2.4(i) namely that function (23) is a smooth solution to the scattering problem (5), (6).

Note that \( \hat{u}_s = \hat{u} - \hat{u}_{in} \) by (45). We will study the function
\[
u_s(\rho, \theta, t) := F_{\omega \rightarrow 1}^{-1}[\hat{u}_s(\rho, \theta, \omega)] \quad (64)
\]
where
\[
\hat{u}_s = \hat{g}(\omega) \mathcal{S}_s(\rho, \theta, \omega) \quad (65)
\]
by (45), and the function \( \mathcal{S}_s \) is defined by (46). We will prove that \( u_s(\rho, \theta, t) \) satisfies system (29), (28).

Note that by Lemma 4.2(ii), (iii), formula (46), and the definition of \( \mathcal{S}_{in} \) in (41),
\[
\mathcal{S}_s \in C(\mathcal{O} \times \mathbb{R}), \quad \mathcal{S}_s(\cdot, \cdot, \omega) \in C^\infty(\mathcal{O}), \quad \omega \in \mathbb{C}^+
\]
First, we will study the function
\[
\hat{w}_s(\rho, \theta, \omega) := \hat{g}_1(\omega) \mathcal{S}_s(\rho, \theta, \omega), \quad \omega \in \mathbb{C}^+ \quad (66)
\]
where \( \hat{g}_1(\omega) \) is defined in (14). Let us define the function

\[
\hat{w}_s(\rho, \theta, t) := \mathcal{F}^{-1}_{\omega \to t}[\tilde{w}_s(\rho, \theta, \omega)], \quad t \in \mathbb{R}
\]

(67)

**Lemma 10.1**

For all \( \rho \geq 0 \) and \( \theta \in [\phi, 2\pi] \) there exists the inverse Fourier–Laplace transform \( w_s(\rho, \theta, t) = \mathcal{F}^{-1}_{\omega \to t}[\tilde{w}_s] \) of the function \( \tilde{w}_s(\rho, \theta, \omega) \), and

\[
w_s \in C^\infty(\tilde{Q} \times \mathbb{R})
\]

(68)

\[
w_s(\rho, \theta, t) \in C(\overline{\tilde{Q}} \times \mathbb{R}), \quad |w_s(\rho, \theta, t)| \leq C, \quad t \geq 0
\]

(69)

\[
w_s(\rho, \theta, t) = 0, \quad t < 0
\]

(70)

**Proof**

Lemma 4.2(iii) shows that \( \mathcal{S}(\rho, \theta, \omega) \) is analytic in \( \omega \in \mathbb{C}^+ \). Hence, the function \( \mathcal{S}_s(\rho, \theta, \cdot) = \mathcal{S}(\rho, \theta, \cdot) - \mathcal{S}_{in}(\rho, \theta, \cdot) \) is analytic in \( \omega \in \mathbb{C}^+ \), since \( \mathcal{S}_{in}(\rho, \theta, \omega) = e^{i\rho \cos(\theta-\omega)} \) is analytic in \( \omega \in \mathbb{C} \).

Furthermore, the function \( \mathcal{S}_s = \mathcal{S}_d + \mathcal{S}_r \) is bounded: namely, \( \mathcal{S}_d \) is bounded by Theorem 8.1, and \( \mathcal{S}_r \) is bounded by (41) since

\[
|e^{i\rho \cos(\theta-\theta_1)}| \leq C, \quad \phi \leq \theta \leq \theta_1, \quad \omega \in \overline{\mathbb{C}^+}, \quad \rho \geq 0
\]

\[
|e^{i\rho \cos(\theta-\theta_2)}| \leq C, \quad \theta_2 \leq \theta \leq 2\pi, \quad \omega \in \overline{\mathbb{C}^+}
\]

The estimates hold since \(-\pi/2 < \theta - \theta_l < \pi/2, \quad l = 1, 2\). Namely, \( \phi - \theta_1 < \theta - \theta_1 < 0 \) and \( \phi - \theta_1 = \pi - \phi > -\pi/2 \) by (10) and (4). Similarly, (4) implies that \( \pi < \pi/2 \). Therefore, \( 0 < \theta - \theta_2 < \pi/2 \), since \( \theta_2 = 2\pi - \pi \) by (10).

Hence,

\[
|\mathcal{S}_s(\rho, \theta, \omega)| \leq C, \quad \omega \in \overline{\mathbb{C}^+}
\]

Therefore, \( \tilde{w}_s(\rho, \theta, \omega) \) also is analytic in \( \omega \in \mathbb{C}^+ \) by (15) and

\[
|\tilde{w}_s(\rho, \theta, \omega)| \leq C_N(1 + |\omega|)^{-N}, \quad \omega \in \overline{\mathbb{C}^+}
\]

by (16). Hence, \( w_s \) satisfies (69), (70) by the Paley–Wiener theorem [16].

Moreover, Corollary 9.3, formula (66), and estimate (16) imply that

\[
\left| \frac{\partial^n}{\partial \rho^{n-\delta}} \tilde{w}_s(\rho, \theta, \omega) \right| \leq C_N(\delta, \pi)\rho^{\delta-1} + |\omega|)^{-N}, \quad (\rho, \theta) \in \tilde{Q}
\]

\[
\omega \in \overline{\mathbb{C}^+ \setminus \{0\}}, \quad \rho \geq \delta > 0, \quad \theta \in [0, 2\pi], \quad C_N(\delta, \pi) > 0
\]

Therefore, (68) holds.

In the following proposition we prove, in particular that the function \( u_s(\rho, \theta, t) \), defined by (64), satisfies problem (29), (28).
Proposition 10.2

(i) The function \( u_s(\rho, \theta, t) \) admits the following representation:

\[
\hat{u}_s(\rho, \theta, \omega) = -i \int_0^t e^{i\omega_0(t-\tau)} w_s(\rho, \theta, \tau) \, d\tau, \quad (\rho, \theta) \in Q, \quad t \in \mathbb{R}
\]  \hspace{1cm} (71)

Furthermore,

\[
u_s \in C^\infty(\dot{Q} \times \mathbb{R})
\]  \hspace{1cm} (72)

and for \((\rho, \theta) \in Q,

\[
u_s(\rho, \theta, t) = 0, \quad t < 0 \quad |\nu_s(\rho, \theta, t)| \leq C(1 + t), \quad t \geq 0
\]  \hspace{1cm} (73)

(ii) \( u_s(\rho, \theta, t) \) is a solution of system (29) and initial conditions (28), and

\[
u_s(\rho, \theta, t) \in C(Q \times \mathbb{R})
\]  \hspace{1cm} (74)

Proof

(i) From (65), (66), and (13) we get

\[
\hat{u}_s(\rho, \theta, \omega) = \frac{\hat{w}_s(\rho, \theta, \omega)}{\omega - \omega_0 + i0}, \quad \omega \in \mathbb{C}^+
\]

Hence and from (67)

\[
u_s(\rho, \theta, t) = \mathcal{F}_{\omega \rightarrow t}^{-1} \left[ \frac{1}{\omega - \omega_0 + i0} \right] * w_s(\rho, \theta, t), \quad \omega \in \mathbb{R}, \quad (\rho, \theta) \in Q
\]

Since

\[
\mathcal{F}_{\omega \rightarrow t}^{-1} \left[ \frac{1}{\omega - \omega_0 + i0} \right] = -ie^{-i\omega t \Theta(t)}
\]

then (75), (70) imply that

\[
u_s(\rho, \theta, t) = [-ie^{-i\omega t \Theta(t)}] * w_s(\rho, \theta, t)
\]

Hence, (71) follows.

Now, (72) follows from (68) and representation (71). At last, (73) follows from (69), (70) and (71).

(ii) System (29) holds for \( u_s \) in the classical sense since \( \hat{u}_s \) satisfies (31) by Corollary 5.2, and (72) holds. Identity (28) follows from (73). Finally, (74) follows from (71) and (69).

\[\square\]

Corollary 10.3

The function \( u(\rho, \theta, t) \) defined by (27) belongs to \( C^\infty(\dot{Q} \times \mathbb{R}) \) and satisfies problem (5), (6).

Proof

The inclusion follows from (72), (27) and (1). Equations (5) and (6) for \( u \) follow from (27) and (28), (29) for \( u_s \).

\[\square\]

Thus, we have proved that \( u \) is the classic solution to (7), (6).
The next theorem will complete the proof of Theorem 2.4 (i). Sections 11–14 concern the proof of the following theorem.

**Theorem 10.4**
The function $u_s(\rho, \theta, t)$ belongs to the space $E_{1-(\pi/\Phi),1-(\pi/\Phi)}$.

Now Theorem 2.4(i) follows since Remark 3.1 implies that $u \in E_{1-(\pi/\Phi),1-(\pi/\Phi)}$.

**Proof**
Definition 2.2, (74) and (72) imply that it suffices to prove only estimates (19) for $u_s$. Note, that it suffices to prove the estimate for $u_d = u_s - u_r$ outside the critical directions $\theta = \theta_1, \theta_2$ since the estimates for $u_r$ are trivial. Sections 11–14 concern the proof of estimates (19) for the diffracted wave $u_d(y, t)$.

11. SOMMERFELD–MALYUZHINETS REPRESENTATION FOR THE DIFFRACTED WAVE

In this section, we construct a convenient representation of the diffracted wave

$$u_d := F^{-1}_\omega \hat{u}_d$$

where

$$\hat{u}_d := \hat{g} \mathcal{F}_d$$

(76)

The representation plays a crucial role in the proof of estimates (19) for $u_s(\rho, \theta, t)$.

**Lemma 11.1**
The scattered wave $u_s$ admits the following representation:

$$u_s(\rho, \theta, t) = \begin{cases} u_d(\rho, \theta, t) + u_r(\rho, \theta, t) & \phi \leq \theta \leq \theta_1 \\ u_d(\rho, \theta, t) & \theta_1 \leq \theta \leq \theta_2 \\ u_d(\rho, \theta, t) + u_r(\rho, \theta, t) & \theta_2 \leq \theta \leq 2\pi \end{cases}$$

(77)

**Proof**
First, (65), the second identity of (46), (76), the definition of $\mathcal{F}_s$ in (41) imply that

$$\hat{u}_s(\rho, \theta, \omega) = \begin{cases} u_d(\rho, \theta, \omega) - \hat{g}(\omega) e^{i \rho \cos(\theta - \theta_1)} & \phi \leq \theta \leq \theta_1 \\ u_d(\rho, \theta, \omega) & \theta_1 \leq \theta \leq \theta_1 \\ u_d(\rho, \theta, \omega) - \hat{g}(\omega) e^{i \rho \cos(\theta - \theta_2)} & \theta_2 \leq \theta \leq 2\pi \end{cases}$$

Now representation (77) follows from (43).

**Theorem 11.2**
The diffracted wave $u_d$ admits the following integral representation:

$$u_d(\rho, \theta, t) = \frac{ie^{-i\omega t}}{4\pi} \int_{\mathcal{C}_0} e^{-c_0 \rho \sinh \beta} H(\beta + i\theta) f(t - i\rho \sinh \beta) d\beta, \quad \theta \neq \theta_{1,2}$$

(78)

where $H$ is defined by (20), the contour $\mathcal{C}_0$ is defined by (47) and $f$ is defined by (2).
**Remark 11.3**

Since for $\beta \in C_0$ we have $f(t - i\rho \sinh \beta) = 0$ for $\rho \geq t$, then

$$u_d(\rho, \theta, \cdot) = 0, \quad \rho \geq t$$

(79)

Note, that this corresponds to the fact that the wave scattered by the vertex of the angle attains the point $(\rho, \theta)$ for the time $\rho$, if the velocity of the propagation of the signal is equal to 1.

**Proof of Theorem 11.2**

From (76), (13) we have

$$\hat{u}_d(\rho, \theta, \omega) = \frac{1}{\omega - w_0} w_d(\rho, \theta, \omega), \quad (\rho, \theta) \in \overline{Q}, \quad \omega \in \mathbb{C}^+ \setminus \{w_0\}$$

(80)

where

$$w_d(\rho, \theta, \omega) := \hat{g}_1(\omega) \mathcal{G}_d(\rho, \theta, \omega), \quad \omega \in \mathbb{C}^+$$

(81)

From (15), (16), Lemma 7.2, Theorem 8.1 it follows that $w_d$ is analytic in $\mathbb{C}^+$, infinitely differentiable in $\mathbb{R} \setminus \{0\}$ and admits the following estimate:

$$|w_d(\rho, \theta, \omega)| \leq C_N (1 + |\omega|)^{-N}, \quad (\rho, \theta) \in \overline{Q}, \quad N \in \mathbb{N}$$

Hence, by the Paley–Wiener theorem we obtain that

$$\text{supp } w_d(\rho, \theta, \cdot) \subset [0, \infty)$$

where

$$w_d(\rho, \theta, t) := F_{\omega \to t}^{-1}[w_d(\rho, \theta, \omega)]$$

(82)

From (80) it follows that

$$u_d(\rho, \theta, t) = -i[e^{-i\omega t} \Theta(t)] * w_d(\rho, \theta, t)$$

(83)

Let us calculate $w_d(\rho, \theta, t)$ for $t \geq 0$, and $\theta \neq \theta_1, \theta_2$.

From (82), (81), the definition of $\mathcal{G}_d$ in (41), estimates (33), (16) and the Fubini theorem we have for $t \geq 0, \theta \neq \theta_1, \theta_2$

$$w_d(\rho, \theta, t) = \frac{i}{8 \pi \Phi} \int_{-\infty}^{\infty} e^{-i\rho t} \left[ \hat{g}_1(\omega) \int_{\gamma_0} e^{-i\omega p \sinh \beta} H(\beta + i\theta) \, d\beta \right] \, d\omega$$

$$= \frac{i}{8 \pi \Phi} \int_{\gamma_0} H(\beta + i\theta) \left[ \int_{-\infty}^{\infty} e^{-i\omega (t - i\rho \sinh \beta)} \hat{g}_1(\omega) \, d\omega \right] \, d\beta$$

$$= \frac{i}{4 \Phi} \int_{\gamma_0} H(\beta + i\theta) g_1(t - i\rho \sinh \beta) \, d\beta$$

(84)

where $g_1(t) := F^{-1}_{\omega \to t} [\hat{g}_1(\omega)]$. Note that $t - i\rho \sinh \beta \in \mathbb{R}$ for $\beta \in C_0$ by definition (47) of the contour $C_0$. Furthermore,

$$\text{supp } w_d(\rho, \theta, \cdot) \subset [\rho, +\infty)$$
since \( g_1(t - i \rho \sinh \beta) = 0 \) for \( t \leq \rho \) by (18). Hence, (83) implies that

\[
u_d(\rho, \theta, t) = \begin{cases} 
-ic^{-i\omega t} \int_\rho^t e^{i\omega s} w_d(\rho, \theta, \tau) d\tau, & \rho \leq t \\
0, & \rho > t
\end{cases}
\quad (\rho, \theta) \in \mathcal{O}
\]  

(85)

Substituting (84) in (85), using estimates (33), (16) and the Fubini theorem we obtain for \( \theta \neq \theta_k, k = 1,2 \)

\[
u_d(\rho, \theta, t) = e^{-i\omega t} \int_{\rho_0}^t H(\beta + i\theta) \left[ \int_{\rho}^t e^{i\omega s} g_1(s - i\rho \sinh \beta) ds \right] d\beta, \quad \rho \leq t
\]  

(86)

**Remark 11.4**
The diffracted wave \( u_d(\rho, \theta, t) \) vanishes for \( \rho > t \). This corresponds to the Huygens principle for the scattering by the wedge.

Substituting (17) in (86), we obtain for \( \theta \neq \theta_k, k = 1,2 \),

\[
u_d(\rho, \theta, t) = \frac{ie^{-i\omega t}}{4\Phi} \int_{\rho_0}^t e^{-i\omega \rho \sinh \beta} H(\beta + i\theta) \left[ \int_{\rho}^t f'(s - i\rho \sinh \beta) ds \right] d\beta, \quad \rho \leq t
\]  

Hence, by (2)

\[
u_d(\rho, \theta, t) = \frac{ie^{-i\omega t}}{4\Phi} \int_{\rho_0}^t e^{-i\omega \rho \sinh \beta} H(\beta + i\theta) f(t - i\rho \sinh \beta) d\beta, \quad \rho \leq t
\]  

(87)

Therefore, representation (78) follows from (87), (85) and Remark 11.3. Theorem is proved.

**Corollary 11.5**
The function \( u_d(\rho, \theta, t) \) admits the following representation for \( \theta \neq \theta_1, \theta_2 \):

\[
u_d(\rho, \theta, t) = \frac{ie^{-i\omega t}}{4\Phi} \int_{\mathbb{R}} Z(\beta, \theta) h(\beta, \rho, t) d\beta
\]  

(90)

**Proof**
Note, that \( \sinh \beta = -i \cosh(\text{Re} \, \beta) \) for \( \beta \in \mathcal{C}_0 \). Making the change of variable \( \text{Re} \, \beta \rightarrow \beta \), we obtain from (87), representation (90) for \( \theta \neq \theta_k, k = 1,2 \). The corollary is proved.
12. ESTIMATES FOR DIFFRACTED WAVE

In this section, we start to prove estimates (19) for \( u_d(\rho, \theta, t) \). In Sections 12 and 13, we prove that \( u_d \) is bounded. First, we prove that the function \( u_d \) is bounded beyond the critical directions. Let us choose \( \delta > 0 \) sufficiently small.

**Lemma 12.1**

The function \( u_d(\rho, \theta, t) \) satisfies the following estimate:

\[
|u_d(\rho, \theta, t)| \leq C \delta, \quad t \geq 0
\]

for \( |\theta_k - \theta| \geq \delta > 0, \quad k = 1, 2 \).

**Proof**

Estimate (33) and (88) imply that the function \( Z(\beta, \theta) \) satisfies the estimate of type (33) for \( \beta \in \mathbb{R} \) and \( |\theta - \theta_k| \geq \delta, \quad k = 1, 2 \). Hence, estimate (91) follows from definition (2) of the profile function \( f \), (89) and (90).

Next, let us prove (91) for \( \theta \) close to \( \theta_1 \) or \( \theta_2 \).

**Theorem 12.2**

For \( k = 1, 2 \) the function \( u_d(\rho, \theta, t) \) satisfies estimate (91) for \( |\theta - \theta_k| < \delta \) with some \( \delta > 0 \).

**Proof**

Let us consider the case when

\[
|\theta - \theta_2| < \delta
\]

for some \( \delta > 0 \). The case \( |\theta - \theta_1| < \delta \) is analysed similarly. The second term on the right-hand side of (88) has not a pole for \( \beta \in \mathbb{R} \) and \( \theta \) satisfying (92). Hence, (33) implies that

\[
|H(-5i\pi/2 + \beta + i\theta)| \leq C(\delta)e^{-(\pi/|Re\beta|)|Re\beta|}, \quad \beta \in \mathbb{R}
\]

Representation (90) and (88) imply that

\[
u_d = \frac{ie^{-i\omega t}}{4\Phi} (-v_{d,1} + v_{d,2})
\]

where

\[
v_{d,1}(\rho, \theta, t) = \int_{\mathbb{R}} H(-i\pi/2 + \beta + i\theta)h(\beta, \rho, t) \, d\beta \tag{94}
\]

\[
v_{d,2}(\rho, \theta, t) = \int_{\mathbb{R}} H(-5i\pi/2 + \beta + i\theta)h(\beta, \rho, t) \, d\beta \tag{95}
\]

It suffices to prove estimate (91) for the function \( v_{d,1} \), since the estimate for \( v_{d,2} \) follows from (93) and (89).

Let us split integral (94) into two integrals: one for \( |\beta| \geq 1 \) and second for \( |\beta| \leq 1 \). Estimate (91) for the function

\[
v'_{d,1}(\rho, \theta, t) := \int_{|\beta| \geq 1} H(-i\pi/2 + \beta + i\theta)h(\beta, \rho, t) \, d\beta
\]

\[
(96)
\]
follows from the estimate of the function $h(\beta, \rho, \theta)$ by (33) since $|H(-i\pi/2 + \beta + i\theta)| \leq C_1 e^{-(\pi/3)Re \beta}$ for $|\beta| \geq 1$. It remains to prove (91) for the function

$$v_{d,1}'(\rho, \theta, t) := \int_{|\beta| \leq 1} H(-i\pi/2 + \beta + i\theta)h(\beta, \rho, t) \, d\beta$$

(97)

By definition (20) we have

$$v_{d,1}'(\rho, \theta, t) = -v_{m}(\rho, \theta, t) + v_{b}(\rho, \theta, t)$$

where

$$v_{b}(\rho, \theta, t) = \int_{|\beta| \leq 1} \coth(\beta + i\theta - iz)h(\beta, \rho, t) \, d\beta$$

$$v_{m}(\rho, \theta, t) = \int_{|\beta| \leq 1} \coth[q(-2\pi i + \beta + i\theta + iz)]h(\beta, \rho, t) \, d\beta$$

(98)

Condition (92) implies that

$$\theta = \theta_2 + \varepsilon$$

where $|\varepsilon| < \delta$. Substituting in representations (98) we obtain

$$\tilde{v}_b(\rho, \varepsilon, t) := v_{b}(\rho, \theta_2 + \varepsilon, t) = \int_{|\beta| \leq 1} \coth[q(\beta + i\varepsilon + 2\pi i - 2iz)]h(\beta, \rho, t) \, d\beta$$

$$\tilde{v}_m(\rho, \varepsilon, t) := v_{m}(\rho, \theta_2 + \varepsilon, t) = \int_{|\beta| \leq 1} \coth[q(\beta + i\varepsilon)]h(\beta, \rho, t) \, d\beta$$

(99)

Let us note that the function $\tilde{v}_b(\rho, \varepsilon, t)$ is regular in the point $\varepsilon = 0$ since $\coth[q(\beta + 2\pi i - 2iz + i\varepsilon)]$ does not have a pole for $|\beta| \leq 1$, if $|\varepsilon| \leq \delta = 1/2$. It follows since $\alpha \leq \pi/2$ by (4). Therefore estimate (91) for the function $\tilde{v}_b$ follows since function $h(\beta, \rho, t)$ is bounded.

In contrast, the function $\tilde{v}_m(\rho, \varepsilon, t)$ is singular at the point $\varepsilon = 0$. Nevertheless we will show that estimate (91) holds for this function too.

13. SINGULAR PART OF THE DIFFRACTED WAVE

First we bound function (99) in the simple case when the profile function $f(s) \equiv \Theta(s)$. Then (89) implies that

$$\tilde{v}_m(\rho, \varepsilon, t) = \int_{|\beta| \leq \beta_0} \coth[q(\beta + i\varepsilon)]e^{i\alpha \rho \cosh \beta} \, d\beta$$

where

$$\beta_0 = \min\{1, \beta_0\}$$

(100)

and $\beta_0 = \beta_0(\rho, t) \geq 0$ is defined by

$$t - \rho \cosh \beta_0 = 0$$

(101)
Lemma 13.1
The function \( \tilde{v}_m \) satisfies the following estimate:

\[ |\tilde{v}_m(\rho, \varepsilon, t)| \leq C, \quad t \geq \rho \geq 0, \quad \varepsilon \neq 0 \]

Proof
By (100) it suffices to note that for any \( a \in [0, 1] \) the integral

\[ u_1(\rho, \varepsilon, a) := \int_{|\beta| \leq a} \frac{e^{i\theta_\rho \rho \cosh \beta}}{(\beta + i\varepsilon)} \, d\beta \]

is uniformly bounded with respect to its arguments (see Proposition A.1 in the appendix). The lemma is proved.

Now we bound the function (99) for a general profile function \( f \).

Theorem 13.2
The function \( \tilde{v}_m(\rho, \varepsilon, t) \) satisfies the following estimate:

\[ |\tilde{v}_m(\rho, \varepsilon, t)| \leq C, \quad \rho \geq 0, \quad \varepsilon \neq 0 \quad (102) \]

Proof
It suffices to bound the function

\[ r(\rho, \varepsilon, t) = \int_{|\beta| \leq 1} \frac{h(\beta, \rho, t)}{\beta + i\varepsilon} \, d\beta \quad (103) \]

with \( h \) defined in (89). We give the proof in Lemmas 13.3–13.5. By (89), it suffices to check (102) in the following three regions:

\[ \mathcal{R}_1 := \{(\rho, t): 0 \leq \rho \leq 5\tau_0, \ \rho \leq t\} \]
\[ \mathcal{R}_2 := \{(\rho, t): \rho \geq 5\tau_0, \ t - 2\tau_0 \leq \rho \leq t\} \]
\[ \mathcal{R}_3 := \{(\rho, t): 5\tau_0 \leq \rho \leq t - 2\tau_0\} \]

where \( \tau_0 \) is the same as in (2).

First, we prove the uniform estimate of this function in \( \mathcal{R}_1 \).

Lemma 13.3
The function \( r(\cdot, \varepsilon, \cdot) \) is bounded in \( \mathcal{R}_1 \) uniformly in \( \varepsilon \neq 0 \):

\[ |r(\rho, \varepsilon, t)| \leq C, \quad (\rho, t) \in \mathcal{R}_1, \quad \varepsilon \neq 0 \]

Proof
Represent \( r \) in the form:

\[ r(\rho, \varepsilon, t) = \int_{|\beta| \leq 1} \frac{h(\beta, \rho, t) - h(0, t, \rho)}{\beta + i\varepsilon} \, d\beta + h(0, t, \rho) \int_{|\beta| \leq 1} \frac{1}{\beta + i\varepsilon} \, d\beta \]

The second summand is bounded, because $h(0,t,\rho)$ is bounded by (89) and the integral

$$
\left| \int_{|\beta| \leq 1} \frac{1}{\beta + i \epsilon} \, d\beta \right| = |\arg(\beta + i \epsilon)|_{-1}^{1} \leq \pi, \quad \epsilon \neq 0
$$

Let us consider the first summand. We have

$$
h(\beta, \rho, t) - h(0,t,\rho) = h'(\tilde{\beta}, t, \rho) \beta
$$

where $|\tilde{\beta}| \leq 1$. Calculating the derivative of $h$, we get that there exists $C > 0$:

$$
|h(\beta, \rho, t) - h(0,t,\rho)| \leq C \rho, \quad 0 \leq \rho \leq t, \quad |\beta| \leq 1
$$

(104)

It implies the estimate

$$
\left| \int_{|\beta| \leq 1} \frac{h(\beta, \rho, t) - h(0,t,\rho)}{\beta + i \epsilon} \, d\beta \right| \leq C \rho \int_{|\beta| \leq 1} \frac{|\beta|}{|\beta + i \epsilon|} \, d\beta \leq C_1
$$

since $\rho \leq 5 \tau_0$.

Now we prove the estimate $r(\rho, \varepsilon, t)$ in $\mathcal{R}_2$ near the characteristic of the wave equation.

**Lemma 13.4**

The function $r(\cdot, \varepsilon, \cdot)$ is bounded in $\mathcal{R}_2$ uniformly in $\varepsilon \neq 0$:

$$
|r(\rho, \varepsilon, t)| \leq C, \quad (\rho, t) \in \mathcal{R}_2, \quad \varepsilon \neq 0
$$

(105)

**Proof**

We represent the function $r$ as

$$
r(\rho, \varepsilon, t) := r_1(\rho, \theta, t) + r_2(\rho, \varepsilon, t)
$$

where

$$
r_1(\rho, \varepsilon, t) := \int_{|\beta| \leq 1} \frac{e^{i \omega \rho \cosh \beta}}{\beta + i \epsilon} \tilde{f}(\beta, \rho, t) \, d\beta
$$

(106)

with

$$
\tilde{f}(\beta, \rho, t) := f(t - \rho \cosh \beta) - f(t - \rho)
$$

and

$$
r_2(\rho, \theta, t) := f(t - \rho) \int_{|\beta| \leq 1} \frac{e^{i \omega \rho \cosh \beta}}{\beta + i \epsilon} \, d\beta
$$

Estimate (105) for the function $r_2$ follows from Proposition A.1 of the appendix, since the function $f(t - \rho)$ is bounded. It remains to prove estimate (105) for the function $r_1$.

By (2) the function $f(t - \rho \cosh \beta)$ is equal to 0 for $\cosh \beta \geq t/\rho$. Since $t/\rho \leq 1 + 2 \tau_0/\rho$ for $(\rho, t) \in \mathcal{R}_2$, we have $f(t - \rho \cosh \beta) = 0$ if $\cosh \beta \geq 1 + 2 \tau_0/\rho$. Therefore we can change the
interval of integration in (106) by \([-\beta_2, \beta_2]\), where \(\beta_2 > 0\), and \(\cosh \beta_2 = 1 + (2\tau_0/\rho)\), since \(\beta_2 < 1\) for \(\rho > 5\tau_0\). Thus, the function \(r_1\) is represented in the form

\[
r_1(\rho, \varepsilon, t) := \int_{|\beta| \leq \beta_2} \frac{e^{i\alpha_0 \rho \cosh \beta}}{\beta + i\varepsilon} \tilde{f}(\beta, t, \rho) \, d\beta
\]

(107)

Now we bound the integrand in (107). Using the Lagrange theorem we write

\[
\left| \frac{e^{i\alpha_0 \rho \cosh \beta}}{\beta + i\varepsilon} \tilde{f}(\rho, \beta, t) \right| \leq C\rho \frac{|\beta|}{|\beta + i\varepsilon|} \sinh \tilde{\beta}
\]

(108)

where \(\tilde{\beta} \leq \beta_2\). Note that \(1 + (2\tau_0/\rho) = \cosh \beta_2 \sim 1 + (\beta_2^2/2)\), hence \(\beta_2 \sim 1/\sqrt{\rho}\), since \(\rho \geq 5\tau_0 > 0\). Therefore,

\[
\sinh \tilde{\beta} \leq \sinh \beta_2 \sim \beta_2 \sim \frac{1}{\sqrt{\rho}}
\]

Now, (108) implies that

\[
\left| \frac{e^{i\alpha_0 \rho \cosh \beta}}{\beta + i\varepsilon} \tilde{f}(\rho, \beta, t) \right| \leq C_1 \sqrt{\rho}, \quad \rho \geq 5\tau_0
\]

Therefore, (107) implies that

\[
|r_1(\rho, \varepsilon, t)| \leq C\sqrt{\rho}\beta_2 \leq C_1 \quad \rho \geq 5\tau_0
\]

It remains to prove estimate (105) in the region \(\mathcal{R}_3\) beyond the characteristics. By (2) and (101) we have that

\[
f(t - \rho \cosh \beta) = \begin{cases} 0, & \cosh \beta \geq \cosh \beta_0 \\ 1, & \cosh \beta \leq \frac{t}{\rho} - \frac{\tau_0}{\rho} \end{cases}
\]

(109)

Equation

\[
\cosh \beta_3 = \frac{t}{\rho} - \frac{\tau_0}{\rho}
\]

(110)

admits a solution \(\beta_3 \geq 0\), since \(t/\rho - \tau_0/\rho \geq 1\) in \(\mathcal{R}_3\). Then (109) implies that

\[
f(t - \rho \cosh \beta) = 1 \quad \text{for} \quad |\beta| \leq \beta_3
\]

(111)

Let us denote

\[
f_1(t - \rho \cosh \beta) = \begin{cases} 0, & \beta \geq \beta_0 \\ f(t - \rho \cosh \beta), & \beta \leq \beta_0 \end{cases}
\]

where \(\beta_0\) is defined by (100). Then we can rewrite (103) in the form:

\[
r(\rho, \varepsilon, t) = \int_{|\beta| \leq \beta_0} f_1(\beta, t, \rho) \left( \frac{e^{i\alpha_0 \rho \cosh \beta}}{\beta + i\varepsilon} \right) \, d\beta, \quad \rho \leq t
\]

(112)
Lemma 13.5
The function $r(\cdot, \varepsilon, \cdot)$ is bounded in the region $\mathcal{R}_3$ uniformly in $\varepsilon \neq 0$:

$$|r(\rho, \varepsilon, t)| \leq C, \quad 5\tau_0 \leq \rho \leq t - 2\tau_0, \quad \varepsilon \neq 0$$  \hfill (113)

Proof
Let us denote

$$\bar{\beta}_3 := \min\{1, \beta_3\}, \quad \rho \leq t - \tau_0$$  \hfill (114)

Then for $\rho \leq t - 2\tau_0$ we can rewrite (112) in the form:

$$r(\rho, \varepsilon, t) = \int_{|\beta| \leq \bar{\beta}_3} \frac{e^{i\omega_0 \rho \cosh \beta}}{\beta + i\varepsilon} \, d\beta + \int_{||\beta| - |\beta_0| \leq \bar{\beta}_0} f_1(\beta, t, \rho) \frac{e^{i\omega_0 \rho \cosh \beta}}{\beta + i\varepsilon} \, d\beta$$

The first integral is bounded by Proposition A.1 of the appendix and (114):

$$\left| \int_{|\beta| \leq \bar{\beta}_3} \frac{e^{i\omega_0 \rho \cosh \beta}}{\beta + i\varepsilon} \, d\beta \right| \leq C, \quad \rho \geq 0, \quad \varepsilon \neq 0$$

For the second integral we prove that

$$|A(\rho, \varepsilon, t)| := \left| \int_{||\beta| - |\beta_0| \leq \bar{\beta}_0} f_1(\beta, t, \rho) \frac{e^{i\omega_0 \rho \cosh \beta}}{\beta + i\varepsilon} \, d\beta \right| \leq C, \quad 5\tau_0 \leq \rho \leq t - 2\tau_0$$  \hfill (115)

Let us consider two cases.

I. Let $\bar{\beta}_3 \geq \frac{1}{2}$. Then estimate (115) holds, since $|\beta + i\varepsilon| \geq 1/2$, for $|\beta| \geq \bar{\beta}_3$ and integral (115) is bounded by a constant in view of (109).

II. Let $\bar{\beta}_3(\rho, t) \leq \frac{1}{2}$. Then $\beta_3 \leq \frac{1}{2}$ by (114). Hence $\cosh \beta_3 \leq \cosh \frac{1}{2}$ and $t/\rho \leq \tau_0/\rho + \cosh \frac{1}{2}$ by (110). On the other hand, $\rho \geq 5\tau_0$. Hence $\tau_0/\rho \leq \frac{1}{4} \leq \cosh 1 - \cosh \frac{1}{2}$ and $\tau_0/\rho + \cosh \frac{1}{2} \leq \cosh 1$. Therefore $t/\rho \leq \cosh 1$ and $\beta_0 \leq 1$ by (101). Now, let us check that

$$\frac{\beta_0}{\beta_3} \leq 2$$  \hfill (116)

Namely, (116) is equivalent to $\cosh \beta_0 \leq 2 \cosh \beta_3^2 - 1$. Definitions (101), (110) of $\beta_0$, $\beta_3$ imply that the last inequality is equivalent to $\rho(t + \rho) \leq 2(t - \tau_0)^2$, which holds by hypothesis (113). Therefore, (116) is proved. Now (115), follows since (116) implies that

$$\left| A(\rho, \varepsilon, t) \right| \leq \int_{|\beta| \leq |\beta_0|} \left| \frac{d\beta}{\beta + i\varepsilon} \right| \leq \int_{|\beta| \leq |\beta_0|} \left| \frac{d\beta}{\beta_3} \right|$$

$$\leq \frac{2}{\beta_3} |\beta_0 - \beta_3| \leq 2 \left( 1 + \left| \frac{\beta_0}{\beta_3} \right| \right) \leq 6$$  \hfill (117)

Here we used that $\beta_3 = \bar{\beta}_3$, since $\bar{\beta}_3 \leq \frac{1}{2}$ and $\bar{\beta}_0 = \beta_0$ since $\beta_0 < 1$. Theorem 13.2 is proved.

Thus, we have proved estimate (19) for $u_4$. In the following section we prove the estimate for $\nabla u_4$. \qed

14. DERIVATIVES OF THE DIFFRACTED WAVE

In this section, we finish the proof of Theorem 10.4. Namely, we prove estimates (19) for $\nabla u_d$.

14.1. Beyond the critical directions

In this subsection, we prove that the derivatives of diffracted wave (90) satisfy estimate (19) beyond the critical directions. In the next subsection, we prove that the derivatives of diffracted wave (90) satisfy estimate (19) near the critical directions.

Proposition 14.1

Let $\theta$ satisfy the condition of Lemma 12.1 for some $\delta > 0$. Then the function $u_d(\rho, \theta, t)$ satisfies the following estimate:

$$|\nabla u_d(\rho, \theta, t)| \leq C_0 (1 + t^\varepsilon)(1 + \rho^{-\varepsilon}), \quad 0 < \rho < t \leq 0$$

(118)

where

$$\varepsilon = 1 - \frac{\pi}{\Phi}$$

Proof

(i) First, we check (118) for the radial derivative $(\partial / \partial \rho) u_d(\rho, \theta, t)$. Then we prove this estimate for the angular derivative. To prove this estimate for the radial derivative we consider the radial derivative of the function $v_{d,1}$ from (94) only, since the estimate for the second summand from (95) is proved similarly. Differentiating this function with respect to $\rho$ and using (89), we get

$$\frac{\partial}{\partial \rho} v_{d,1}(\rho, \theta, t) = \left\{ \int_{\mathbb{R}} e^{i\omega_0 \rho \cosh \beta} H(-i\pi/2 + \beta + i\theta) \cosh \beta [i\omega_0 f(t - \rho \cosh \beta)

-f'(t - \rho \cosh \beta)] d\beta \right\}$$

(119)

The integrand in (119) vanished outside the interval $[-\beta_0, \beta_0]$ according to (2) and definition (101). Therefore, (33) implies the following estimate for (119):

$$\left| \frac{\partial}{\partial \rho} v_{d,1}(\rho, \theta, t) \right| \leq C_0 \int_0^{\beta_0} e^{\beta(1 - (t/\rho))} d\beta$$

(120)

Definition (101) gives that

$$\beta_0 = \ln \left( \frac{t + \sqrt{t^2 - \rho^2}}{\rho} \right)$$

Hence, (120) implies the following estimate:

$$\left| \frac{\partial}{\partial \rho} v_{d,1}(\rho, \theta, t) \right| \leq C \left[ \left( \frac{t + \sqrt{t^2 - \rho^2}}{\rho} \right)^\varepsilon \right]^{\varepsilon}, \quad \rho \leq t$$

(121)
The estimate \((t + \sqrt{t^2 - \rho^2}) \leq 2(1 + t)\) implies the estimate \((t + \sqrt{t^2 - \rho^2})^\varepsilon \leq C(1 + t^\varepsilon)\). Hence and from (121) we obtain

\[
\left| \frac{\partial}{\partial \rho} v_{d,1}(\rho, \theta, t) \right| \leq C[(1 + t^\varepsilon)(1 + \rho^{-\varepsilon}) + (1 + \rho^{-\varepsilon})], \quad \rho \leq t
\]  

(122)

Now, estimate (118) follows for \(C_\delta := 2C\). The statement (i) is proved.

(ii) Let us prove estimate (118) for the angular derivative of the function \(u_d\). As in the proof (i) it suffices to prove this estimate for \((1/\rho) v_{d,1}(\rho, \theta, t)\). Differentiating function (94) with respect to \(\theta\), noting, that

\[
\frac{\partial}{\partial \theta} H(-i\pi/2 + \beta + i\theta) = (-i) \frac{\partial}{\partial \beta} H(-i\pi/2 + \beta + i\theta) f(t - \rho \cosh \beta) d\beta
\]

we obtain:

\[
\frac{1}{\rho} \frac{\partial}{\partial \theta} v_{d,1}(\rho, \theta, t) = -\frac{i}{\rho} \int_{\mathbb{R}} e^{i\omega_0 \rho \cosh \beta} \frac{\partial}{\partial \beta} H(-i\pi/2 + \beta + i\theta) f(t - \rho \cosh \beta) d\beta
\]  

(123)

Integrating by parts in (123), and using that the function \(f(t - \rho \cosh \beta) \in C_0^\infty(\mathbb{R})\) we obtain

\[
\frac{1}{\rho} \frac{\partial}{\partial \theta} v_{d,1}(\rho, \theta, t) = i \int_{\mathbb{R}} e^{i\omega_0 \rho \cosh \beta} H(-i\pi/2 + \beta + i\theta) \sinh \beta[i\omega_0 f(t - \rho \cosh \beta) - f'(t - \rho \cosh \beta)] d\beta
\]  

(124)

Thus, we have obtained the expression similar to (119) and applying the same arguments as in the proof of (i) we obtain estimate (118) for the derivative \((1/\rho)(\partial/\partial \theta)v_{d,1}(\rho, \theta, t)\). The proposition is proved.

14.2. Near the critical directions

In this section, we obtain estimate (118) for \(\theta\) close to \(\theta_1\) and \(\theta_2\).

**Proposition 14.2**

Estimate (118) holds for \(|\theta - \theta_k| < \delta, k = 1, 2\) for sufficiently small \(\delta > 0\).

**Proof**

First, we prove estimate (118) for the radial derivative. We suppose that \(\theta\) satisfies (92). The case when \(\theta\) is close to \(\theta_1\) is considered similarly. As in Proposition 14.1, we check this estimate for \(\partial v_{d,1}/\partial \rho\) from (119). This function is the sum of the functions \(w'_{d,1}\) and \(w''_{d,2}\), where

\[
w'_{d,1}(\rho, \theta, t) := \int_{|\beta| < 1} e^{i\omega_0 \rho \cosh \beta} H(-i\pi/2 + \beta + i\theta) \cosh \beta[i\omega_0 f(t - \rho \cosh \beta) - f'(t - \rho \cosh \beta)] d\beta
\]  

(125)

and

\[
w''_{d,1}(\rho, \theta, t) := \int_{|\beta| \geq 1} e^{i\omega_0 \rho \cosh \beta} H(-i\pi/2 + \beta + i\theta) \cosh \beta[i\omega_0 f(t - \rho \cosh \beta) - f'(t - \rho \cosh \beta)] d\beta
\]  

(126)
The functions $w_{d,1}'$ and $w_{d,2}''$ are similar to the functions $v_{d,1}'$ and $v_{d,2}''$ from (97) and (96). The difference is that the function $h$ from (89) is changed by the function
\[ g(\beta, \rho, t) := e^{i\omega_0 \rho \cosh \beta} \cosh \beta[f(t - \rho \cosh \beta) - f(t - \rho \cosh \beta) - f'(t - \rho \cosh \beta)] \quad \beta \in \mathbb{R}, \ \rho \leq t \]
(127)
The function $w_{d,1}''$ satisfies estimate (118). In effect, it is obtained from the estimate of type (120) for the function $(\partial \partial / \partial \partial)w_{d,1}(\rho, \theta, t)$ from (119), where instead of the integrating over $[0, \beta_0]$ it is necessary to integrate over $[1, \beta_0]$.

Let us prove the estimate for $w_{d,1}'$. Similarly to (97)–(99) we reduce this problem to the estimate of the function
\[ \tilde{w}_{d,1}(\rho, \varepsilon, t) := \int_{|\beta| \leq 1} \coth[q(\beta + i\varepsilon)]g(\beta, t, \rho) \, d\beta \]
Similarly to Lemma 13.1, we reduce the problem to the function
\[ b(t, \rho, \varepsilon) := \int_{|\beta| \leq 1} \frac{g(\beta, t, \rho)}{\beta + i\varepsilon} \, d\beta \]
This function is similar to the function $r(\rho, \varepsilon, t)$ from (103). The difference is that the function $h$ in (103) is changed by the function $g$ from (127).

**Proposition 14.3**
\[ |b(\rho, \varepsilon, t)| \leq C, \ \varepsilon \neq 0, \ 0 \leq \rho \leq t \]

**Proof**
The proof is similar to the proof of Theorem 13.2. We analyse Lemmas 13.3–13.5. The proof of Lemma 13.3 serves for the this case since $g$ admits the estimate of type (104):
\[ |g(\beta, \rho, t) - g(0, \rho, t)| \leq C\rho, \ 0 \leq \rho \leq t, \ |\beta| \leq 1 \]
The proof of Lemma 13.4 also serves since the function $\tilde{g} := g(t - \rho \cosh \beta) - g(t - \rho)$ admits estimate (108). Finally, since the function $g$ is bounded, then the proof of Lemma 13.5 for $b(\rho, \varepsilon, t)$ is reduced to the estimate of the function $A(\rho, \varepsilon, t)$ from (117). Thus, the proposition and Proposition 14.2 are proved for the radial derivative.

Now, we prove the estimate for the angular derivative $(1/\rho)(\partial / \partial \theta)w_{d,1}(\rho, \theta, t)$. Let us consider expression (124). Similarly to the case of the radial derivative, we represent this expression as the sum of the integral of types (125) and (126). The integral over $|\beta| > 1$ is bounded similarly to the function $w_{d,2}''(\rho, \theta, t)$. The estimate of the same integral over $|\beta| \leq 1$ is trivial, since $|\sinh \beta/(\beta + i\varepsilon)| \leq C, \ |\beta| \leq 1$.

Thus, we have proved completely estimate (118). Together with the results of Sections 12 and 13, it implies estimate (19) for the function $u_\varepsilon$. Theorems 10.4 and 2.4(i) are proved.

In next section we finish the proof of Theorem 2.4.

### 15. LIMITING AMPLITUDE PRINCIPLE

Here we prove the Limiting Amplitude principle (26), i.e.
\[ u(\rho, \theta, t) \sim A(\rho, \theta)e^{-i\omega_0 t}, \ t \to \infty \]
(128)
Let us consider the function
\[ u(y,t) = u_{in}(y,t) + u_{r}(y,t) + u_{d}(y,t) \] (129)
which is a solution of nonstationary problem (5), (6) given by (23), with \( u_{in}, u_{r}, u_{d} \) given by (1), (9)–(11) and (90), respectively. Equations (1), (9)–(11) imply that for any \( \rho_0 > 0 \)
\[ u_{in} = A_{in}(\rho, \theta)e^{-i\omega_0 t}, \quad u_{r} = A_{r}(\rho, \theta)e^{-i\omega_0 t}, \quad t \geq \tau_0 + \rho_0, \quad \rho \leq \rho_0 \] (130)
where
\[ A_{in}(\rho, \theta) := e^{i\omega_0 \rho \cos(\theta - z)} \]
\[ A_{r}(\rho, \theta) = \begin{cases} e^{i\omega_0 \rho \cos(\theta - \theta_1)}, & \phi \leq \theta \leq \theta_1 \\ 0, & \theta_1 < \theta < \theta_2 \\ e^{i\omega_0 \rho \cos(\theta - \theta_2)}, & \theta_2 \leq \theta \leq 2\pi \end{cases} \] (131)
and \( \theta_1, \theta_2 \) are defined by (10). It remains to check the asymptotics of type (128) for the diffracted wave \( u_{d}(\rho, \theta, t) \) given by (90), with the corresponding limiting amplitude
\[ A_{d}(\rho, \theta) := \frac{i}{4\Phi} \int_{R} e^{i\omega_0 \rho \cosh \beta} Z(\beta, \theta) d\beta, \quad (\rho, \theta) \in Q \] (132)
where \( Z \) is defined by (88).

**Theorem 15.1**

For any \( \rho_0 > 0 \) the following asymptotics hold:
\[ u_{d}(\rho, \theta, t) - A_{d}(\rho, \theta)e^{-i\omega_0 t} \rightarrow 0, \quad t \rightarrow \infty \]
uniformly in \( \rho \in [0, \rho_0] \) and \( \theta \in [\phi, 2\pi] \).

**Proof**

Equation (90) implies that
\[ A_{d}(\rho, \theta, t) := e^{i\omega_0 t} A_{d}(\rho, \theta, t) = \frac{i}{4\Phi} \int_{R} Z(\beta, \theta) h(\beta, \rho, \theta) d\beta \] (133)
It remains to prove that
\[ A_{d}(\rho, \theta, t) \rightarrow A_{d}(\rho, \theta), \quad t \rightarrow \infty \]
uniformly with the respect to \( \rho \leq \rho_0 \). Formulas (132) and (133) imply that
\[ A_{d}(\rho, \theta, t) - A_{d}(\rho, \theta) = \frac{i}{4\Phi} \int_{R} [Z(\beta, \theta) h(\beta, \rho, t) - Z(\beta, \theta) e^{i\omega_0 \rho \cosh \beta}] d\beta \]
Let us fix \( \rho_0 > 0 \) and \( \varepsilon > 0 \). Let us choose \( |\beta| \geq 1 \) such that
\[ \frac{8C_1 \Phi e^{-(\varepsilon/\Phi)|\beta|}}{\pi} < \varepsilon \]
where $C_1$ is the constant from (33). Then by (88), (33) and (2)

$$
\int_{|\beta|<\beta_0} |Z(\beta, \theta)h(\beta, \rho, t) - Z(\beta, \theta)e^{i\omega_0 \rho \cosh \beta_0}| < 8C_1 \int_{|\beta|>\beta_0} e^{-(\sigma/\Phi)|\beta|} \leq 8C_1 \frac{\Phi e^{-(\sigma/\Phi)|\beta|}}{\pi} < \varepsilon, \quad t \in \mathbb{R}
$$

(134)

It remains to prove the convergence to zero of the integral over $|\beta|<\beta_0$. First, $\cosh \beta_3(\rho, \theta) = (t - \tau_0)/\rho \geq \cosh \beta_0$, for $t \geq \tau_0 + \rho \cosh \beta_0$, where $\beta_3$ is defined by (110). This implies that $f(t - \rho \cos \beta) = 1$ for $|\beta|<\beta_0$ by (111). Hence

$$
\int_{|\beta|<\beta_0} |Z(\beta, \theta)h(\beta, \rho, t) - Z(\beta, \theta)e^{i\omega_0 \rho \cosh \beta_0}| \, d\beta = 0 < \varepsilon, \quad t \geq \tau_0 + \rho_0 \cosh \beta_0, \quad \rho \leq \rho_0
$$

Therefore, (134) implies that

$$
\int_{|\beta| \geq \beta_0} |Z(\beta, \theta)h(\beta, \rho, t) - Z(\beta, \theta)e^{i\omega_0 \rho \cosh \beta_0}| \, d\beta < \varepsilon, \quad t \geq \tau_0 + \rho_0 \cosh \beta, \quad \rho \leq \rho_0
$$

The theorem is proved.

Proof of Theorem 2.4

(ii) Using the Cauchy Residue theorem, we split the limiting amplitude $A(\rho, \theta)$, given by (25), into three summands, similarly to the splitting of the function $\mathscr{S}(\rho, \theta, \omega)$ in Lemma 7.2. So, we obtain that

$$
A(\rho, \theta) = A_{in}(\rho, \theta) + A_r(\rho, \theta) + A_d(\rho, \theta)
$$

where $A_{in}, A_r, A_d$ are given by (131) and (132). Here representation (132) for $A_d$ is obtained similarly to the derivation from (41) of representation (90) for $\mathscr{S}_d$. Now, statement (ii) of Theorem 2.4 follows from (129), (130), and Theorem 15.1.

Remark 15.2

Expression (25) coincides with the well-known Sommerfeld–Malyuzhinets formula [7,8,17]. It is known (see, for example Reference [6]) that it is the unique solution of the stationary diffraction problem

$$
\begin{align*}
(\Delta + \omega_0^2)A(\rho, \theta) &= 0, \quad (\rho, \theta) \in \Omega \\
A|_{\partial \Omega} &= 0
\end{align*}
$$

satisfying the following conditions:

1. $A \in C(\Omega)$, $A \in C^2(\Omega)$.
2. The Meixner condition holds in some neighbourhood of the vertex: $A(\rho, \theta) = O(\rho^{\pi/2\Phi})$, $\rho \to 0$
3. The limiting amplitude $A_d(\rho, \theta) := A - A_{in} - A_r$ of the diffracted wave, satisfies the Sommerfeld radiation condition [6–8,17].
APPENDIX A: OSCILLATORY CAUCHY-TYPE INTEGRALS

Let us consider the following singular Fresnel integrals:

\[ \psi_1(z, \varepsilon, a) := \int_{-a}^{a} \frac{e^{izt^2}}{t + i\varepsilon} \, dt, \quad \psi_2(z, \varepsilon, a) := \int_{-a}^{a} \frac{e^{izt}}{t + i\varepsilon} \, dt \]

We have used the following well-known estimates.

**Proposition A.1** (Bleistein [18] and Fedoryuk [14])

(i) The function \( \psi_1(z, \varepsilon, a) \) is uniformly bounded:

\[ |\psi_1(z, \varepsilon, a)| \leq C, \quad z \geq 0, \quad 0 \leq a \leq 1, \quad \varepsilon \neq 0 \]

(ii) The function \( \psi_2(z, \varepsilon, a) \) is uniformly bounded:

\[ |\psi_2(z, \varepsilon, a)| \leq C, \quad z \geq 0, \quad 0 \leq a \leq 1, \quad \varepsilon \neq 0 \]
