# ON PARITY AND CHARACTERS OF SYMMETRIC GROUPS 

ALEXANDER R. MILLER

#### Abstract

We present a conjectural parity bias in the character values of the symmetric group. The main conjecture says that a character value chosen uniformly at random from the character table of $S_{n}$ is congruent to 0 mod 2 with probability $\rightarrow 1$ as $n \rightarrow \infty$. A more general conjecture says that the same is true for all primes $p$, not only $p=2$. We relate these conjectures to zeros, give generating functions for computing lower bounds, and present some computational data in support of the main conjecture.

## 1. Introduction

This note is a sequel to [11] where we studied zeros and random character values of the symmetric group $S_{n}$. By character we mean irreducible character. The purpose of this short note is to present two conjectures. The first and main conjecture (Conjecture 1) says that a character value chosen uniformly at random from the character table of $S_{n}$ is congruent to $0 \bmod 2$ with probability $\rightarrow 1$ as $n \rightarrow \infty$. The second conjecture (Conjecture 2 ) says that the same is true for all primes $p$, not only $p=2$. It should be stated here at the start that we are unable to prove these conjectures.
1.1. Character values of $\mathbf{S}_{\mathbf{n}}$. Given an integer partition $\lambda$ of $n$, let $\chi_{\lambda}$ be the corresponding irreducible character of $S_{n}$, and let $\chi_{\lambda}(\mu)$ be short for the value of $\chi_{\lambda}$ at any $g$ with cycle type $\mu$, so that the matrix $\left[\chi_{\lambda}(\mu)\right]_{\lambda, \mu}$ is the character table of $S_{n}$ [8]. These values can be computed for small $n$ with the formulas of Frobenius and Murnaghan-Nakayama. Frobenius [3] says

$$
\begin{equation*}
\chi_{\lambda}(\mu)=\text { coeff. of } x_{1}^{n+\lambda_{1}-1} x_{2}^{n+\lambda_{2}-2} \ldots x_{n}^{\lambda_{n}} \text { in } \Delta(x) P_{\mu}(x) \tag{1}
\end{equation*}
$$

where $\Delta(x)=\prod_{1 \leq i<j \leq n}\left(x_{i}-x_{j}\right)$ and $P_{\mu}(x)=P_{\mu_{1}}(x) P_{\mu_{2}}(x) \ldots P_{\mu_{n}}(x), P_{0}(x)=1$, $P_{k}(x)=x_{1}^{k}+x_{2}^{k}+\ldots+x_{n}^{k}$ for $k \geq 1$. Murnaghan-Nakayama says

$$
\begin{equation*}
\chi_{\lambda}(\mu)=\sum(-1)^{\mathrm{ht}(\rho)} \chi_{\lambda \backslash \rho}(\nu) \tag{2}
\end{equation*}
$$

for any $v$ obtained by removing a nonzero part from $\mu$, where the sum is over all rim hooks $\rho$ in $\lambda$ of size $|\mu|-|\nu|$, and $\operatorname{ht}(\rho)$ is one less than the number of rows occupied by $\rho$, see [8].
1.2. Background. The study of zeros of irreducible characters goes back to Burnside [2], who proved that each nonlinear irreducible character of a finite group is zero on some class. J. G. Thompson modified Burnside's argument to prove that for each irreducible character the values are roots of unity or zero on more than a third of the group [7, p. 46]. P. X. Gallagher proved similarly that on a larger than average class some irreducible character is zero [4], and that on a larger than average class the character values are roots of unity or zero for more than a third of the irreducible characters [5].

What can be said about a random character value of the symmetric group? Here there are two natural ways to choose a character value. The first is to choose $\chi$ uniformly at

[^0]random from the irreducible characters and $g$ uniformly at random from the group, and then evaluate $\chi(g)$. The main result of [11] is the remarkable fact that for the symmetric group $S_{n}$ the probability that $\chi(g)$ equals 0 goes to 1 as $n \rightarrow \infty$ [11, Theorem 1].

The other natural way to choose a character value of $S_{n}$ is to choose an entry $\chi_{\lambda}(\mu)$ uniformly at random from the character table. That is, choose $\lambda$ and $\mu$ uniformly at random from the partitions of $n$, and then evaluate $\chi_{\lambda}(\mu)$. In this scheme the asymptotic behavior of $\operatorname{Prob}\left(\chi_{\lambda}(\mu)=0\right)$ is not known, and experiments do not suggest a limit of 1 . See Table 3 in Section 4 and cf. [11, Question 2 and p. 1015].
1.3. Working modulo 2. The present note considers zeros of $S_{n}$ character values mod 2 . In particular, we are interested in the asymptotic behavior of $\operatorname{Prob}\left(\chi_{\lambda}(\mu) \equiv 0(\bmod 2)\right)$. What we find experimentally is a striking parity bias. See Figure 1.

Figure 1. $\operatorname{Prob}\left(\chi_{\lambda}(\mu) \equiv 0(\bmod 2)\right)$ for $1 \leq n \leq 76$.

Conjecture 1. $\operatorname{Prob}\left(\chi_{\lambda}(\mu) \equiv 0(\bmod 2)\right) \rightarrow 1$ as $n \rightarrow \infty$.
Our second conjecture extends the first to other primes.
Conjecture 2. $\operatorname{Prob}\left(\chi_{\lambda}(\mu) \equiv 0(\bmod p)\right) \rightarrow 1$ as $n \rightarrow \infty$ for every prime $p$.
Numerical evidence for Conjectures 1 and 2 is given in Section 4 in Tables 1 and 2. Table 1 lists the number of even entries in the character table of $S_{n}$ for $1 \leq n \leq 76$. Table 2 lists $\operatorname{Prob}\left(\chi_{\lambda}(\mu) \equiv 0(\bmod q)\right)$ for some small prime powers $q$ and $1 \leq n \leq 38$. In Section 2 we relate Conjecture 1 and Conjecture 2 to zeros in the character table of $S_{n}$. We use a small set of well-understood zeros to obtain generating functions for computing lower bounds for the number of $\chi_{\lambda}(\mu)$ 's congruent to $0 \bmod p$. These crude bounds are surprisingly good. However, it seems that new tools will be needed in order to establish a parity bias, see Remark 1. In Section 3 we make two more remarks. The first remark reformulates Conjecture 1 as a problem in tableau enumeration, see Conjecture $1^{\prime}$. This gives another possible approach to Conjecture 1. The second remark explains why in Table 1 we find that the number of even entries in the character table of $S_{n}$ is always even.

## 2. Zeros and a lower bound

2.1. The following is a well-known result for dealing with characters of $S_{n}$ modulo a prime number $p$. See [12, §3] and [10, Proof of Theorem].
Proposition 1. Let $\chi$ be a character of $S_{n}$, and let $p$ be a prime number. Suppose that $\mu$ and $v$ are partitions of $n$ such that $v$ is obtained from $\mu$ by replacing $p$ parts of size $k$ with a single part of size $p k$. Then $\chi(\mu) \equiv \chi(\nu)(\bmod p)$.

Proof. This follows from Frobenius (1) and $(x+y)^{p}=x^{p}+y^{p}$ over $\mathbf{Z} / p \mathbf{Z}$.
2.2. Consider the graph $\Gamma_{p}(n)$ whose vertices are the partitions $\mu$ of $n$, and whose edges are the pairs $\{\mu, \nu\}$ where $v$ is obtained from $\mu$ by exchanging $p$ parts of size $k$ for a part of size $p k$. Let

$$
\begin{align*}
& \operatorname{Par}(n)=\{\text { partitions of } n\}  \tag{3}\\
& \Omega_{p}(n)=\{\text { partitions of } n \text { into parts not divisible by } p\}  \tag{4}\\
& \Delta_{p}(n)=\{\text { partitions of } n \text { with no part appearing } p \text { or more times }\} \tag{5}
\end{align*}
$$

Each connected component of $\Gamma(n)$ contains a unique representative $\mu \in \Delta_{p}(n)$ and a unique representative $\mu^{*} \in \Omega_{p}(n)$. The partition $\mu^{*}$ is obtained from $\mu$ by replacing each part $p^{k} d(p \nmid d)$ by $p^{k}$ parts of size $d$, and this mapping $\mu \mapsto \mu^{*}$ is a bijection from $\Delta_{p}(n)$ onto $\Omega_{p}(n)$. (The $p=2$ case of this is the odd-distinct bijection of Euler [1].) Write $K_{p}(\mu)\left(\mu \in \Delta_{p}(n)\right)$ for the set of partitions in the same component as $\mu$, so that

$$
\begin{equation*}
\operatorname{Par}(n)=\bigcup_{\mu \in \Delta_{p}(n)} K_{p}(\mu) \tag{6}
\end{equation*}
$$

as a disjoint union, and $\mu, \mu^{*} \in K_{p}(\mu)$. Let $k_{p}(\mu)=\left|K_{p}(\mu)\right|$ and let

$$
\begin{align*}
N_{p}(n) & =\#\left\{(\lambda, \mu) \in \operatorname{Par}(n) \times \operatorname{Par}(n): \chi_{\lambda}(\mu) \equiv 0(\bmod p)\right\}  \tag{7}\\
z_{p}(\mu) & =\#\left\{\lambda \in \operatorname{Par}(n): \chi_{\lambda}(\mu) \equiv 0(\bmod p)\right\}  \tag{8}\\
z(\mu) & =\#\left\{\lambda \in \operatorname{Par}(n): \chi_{\lambda}(\mu)=0\right\} \tag{9}
\end{align*}
$$

Proposition 2.

$$
\begin{equation*}
N_{p}(n)=\sum_{\mu \in \Delta_{p}(n)} k_{p}(\mu) z_{p}(\mu) \tag{10}
\end{equation*}
$$

and

$$
\begin{equation*}
N_{p}(n) \geq \sum_{\mu \in \Delta_{p}(n)} k_{p}(\mu) z(\mu) \tag{11}
\end{equation*}
$$

Proof. Proposition 1 implies (10), and (11) follows.
What makes Proposition 2 useful is: $\Delta_{p}(n)$ is much smaller than $\operatorname{Par}(n)$, the numbers $k_{p}(\mu)$ are straightforward to compute (Proposition 3), and even crude lower bounds on the number of zeros $z(\mu)$ in the $\mu$ column of the character table of $S_{n}$ result in good lower bounds on the number $N_{p}(n)$ of $p$-divisible entries in the character table (Theorem 1).
2.3. Let $\mu=1^{m_{1}} 2^{m_{2}} \ldots n^{m_{n}}$ be shorthand for the partition $\mu$ with $m_{1}$ many 1 's, $m_{2}$ many 2's, and so on. Let $a_{p}(n)$ be the number of partitions of $n$ into powers of $p$, so that

$$
\begin{equation*}
\sum_{n=0}^{\infty} a_{p}(n) q^{n}=\prod_{j=0}^{\infty} \frac{1}{1-q^{p^{j}}} \tag{12}
\end{equation*}
$$

and $a_{p}(n)$ is given by the recurrence relation

$$
a_{p}(n)= \begin{cases}a_{p}(n-1) & \text { if } n \not \equiv 0(\bmod p)  \tag{13}\\ a_{p}(n-1)+a_{p}(n / p) & \text { if } n \equiv 0(\bmod p)\end{cases}
$$

where $a_{p}(0)=a_{p}(1)=\ldots=a_{p}(p-1)=1$. See [13]. Then we have the following formula for $k_{p}(\mu)$.

Proposition 3. Let $\mu \in \Delta_{p}(n)$ and write $\mu^{*}=1^{m_{1}} 2^{m_{2}} \ldots n^{m_{n}}$. Then

$$
\begin{equation*}
k_{p}(\mu)=a_{p}\left(m_{1}\right) a_{p}\left(m_{2}\right) \ldots a_{p}\left(m_{n}\right) \tag{14}
\end{equation*}
$$

Proof. Define

$$
\begin{equation*}
\pi: \operatorname{Par}(n) \rightarrow \Omega_{p}(n), \quad 1^{s_{1}} 2^{s_{2}} \ldots n^{s_{n}} \mapsto \prod_{p \nmid k} k^{s_{k}+p s_{k p}+p^{2} s_{k p^{2}}+\ldots} \tag{15}
\end{equation*}
$$

Then

$$
\begin{equation*}
K_{p}(\mu)=\pi^{-1}\left(\mu^{*}\right) \tag{16}
\end{equation*}
$$

and the elements of $\pi^{-1}\left(\mu^{*}\right)$ are in bijection with the tuples $\left(v_{1}, v_{2}, \ldots, v_{n}\right)$ where $v_{k}$ is a partition of $m_{k}$ into powers of $p\left(s_{k}\right.$ many 1 's, $s_{k p}$ many $p$ 's, and so on).
2.4. By $t$-core we mean a partition $\lambda$ with no rim hook of size $t$, which is the same as saying that $\lambda$ has no hook of size $t$ (cf. [8, pp. 76 and 56]), or equivalently $\lambda$ has no hook of size divisible by $t$ [8, p. 86]. Let $c_{t}(n)$ be the number of $t$-core partitions of $n$. Then [6, 9]

$$
\begin{equation*}
\sum_{n=0}^{\infty} c_{t}(n) q^{n}=\prod_{n=1}^{\infty} \frac{\left(1-q^{t n}\right)^{t}}{\left(1-q^{n}\right)} \tag{17}
\end{equation*}
$$

## Theorem 1.

$$
\begin{equation*}
N_{p}(n) \geq \sum_{t=1}^{n} c_{t}(n) \sum_{\substack{\mu \in \Delta_{p}(n) \\ \mu_{1}=t}} k_{p}(\mu) . \tag{18}
\end{equation*}
$$

Proof. Let $\lambda, \mu \in \operatorname{Par}(n)$. If $\lambda$ is a $t$-core and $\mu$ has a part of size $t$, then by the MurnaghanNakayama rule $\chi_{\lambda}(\mu)=0$. In particular, the number of 0 's in column $\mu$ of the $S_{n}$ character table is bounded below by the number of $\mu_{1}$-core partitions of $n$. In other words, $z(\mu) \geq$ $c_{\mu_{1}}(n)$. This inequality and the one in (11) together give the result.

Remark 1. We suspect that Theorem 1 can be used to obtain nontrivial asymptotic lower bounds for $\operatorname{Prob}\left(\chi_{\lambda}(\mu) \equiv 0(\bmod 2)\right)$. For example, for $n=30,60,90,120$ the respective lower bounds for $\operatorname{Prob}\left(\chi_{\lambda}(\mu) \equiv 0(\bmod 2)\right)$ given by Theorem 1 are approximately $0.45369,0.47022,0.47883$, and 0.46521 . Unfortunately, at least from these computations, Theorem 1 does not seem sufficient for a provable parity bias in the sense that there exists an $\epsilon>0$ such that $\operatorname{Prob}\left(\chi_{\lambda}(\mu) \equiv 0(\bmod 2)\right) \geq 1 / 2+\epsilon$ for $n$ sufficiently large.

## 3. Remarks

3.1. Conjecture 1 can be reformulated as a problem in tableau enumeration. Let $N_{\lambda \mu}$ be the number of rim hook tableaux of shape $\lambda$ and content $\mu$, see [14].

Proposition 4. $\chi_{\lambda}(\mu) \equiv N_{\lambda \mu}(\bmod 2)$.
Proof. By the Murnaghan-Nakayama rule (2).

Hence the following enumerative reformulation of Conjecture 1.
Conjecture 1'. $\operatorname{Prob}\left(N_{\lambda \mu}\right.$ is even $) \rightarrow 1$ as $n \rightarrow \infty$.
3.2. We are aware of one previous parity result for the character table of $S_{n}$. It is an enumerative result on the number of odd entries in the column of degrees $\chi_{\lambda}\left(1^{n}\right)$. J. McKay [10] proved that the number of odd entries in this column is a certain power of 2. It is natural to wonder about a similar result for the entire character table. Table 1 suggests that the number of even entries is always even. This is in fact true.
Theorem 2. The number of even entries $\chi_{\lambda}(\mu)$ in the character table of $S_{n}$ is even.
Recall that the conjugate of $\lambda$ is the partition $\lambda^{\prime}$ whose parts are $\lambda_{i}^{\prime}=\#\left\{j: i \leq \lambda_{j}\right\}$ for $1 \leq i \leq \lambda_{1}$. Conjugation is the involution $\lambda \mapsto \lambda^{\prime}$. The fixed points of this involution are self-conjugate partitions. Self-conjugate partitions $\lambda$ of $n$ are in one-to-one correspondence with partitions $\mu$ of $n$ into odd distinct parts via $\lambda \mapsto \mu$ where $\mu_{i}=2\left(\lambda_{i}-i\right)+1$ for $i$ such that $1 \leq i \leq \lambda_{i}$.

Proof of Theorem 2. Let $O_{n}$ be the number of odd entries in the character table of $S_{n}$. Then

$$
\begin{equation*}
O_{n} \equiv \sum_{\mu} \sum_{\lambda} \chi_{\lambda}(\mu) \equiv \sum_{\mu} \sum_{\lambda} \chi_{\lambda}(\mu)^{2}(\bmod 2) \tag{19}
\end{equation*}
$$

where the sums are over all partitions of $n$. By one of the orthogonality relations [3]

$$
\begin{equation*}
\sum_{\lambda} \chi_{\lambda}(\mu)^{2}=1^{m_{1}} m_{1}!2^{m_{2}} m_{2}!\ldots n^{m_{n}} m_{n}! \tag{20}
\end{equation*}
$$

where $m_{i}$ is the number of $i$ 's in $\mu$. Together (19) and (20) imply that

$$
\begin{equation*}
O_{n} \equiv O D_{n}(\bmod 2) \tag{21}
\end{equation*}
$$

where $O D_{n}$ is the number of partitions of $n$ into odd distinct parts. Let $S C_{n}$ be the number of self-conjugate partitions of $n$ so that $S C_{n}=O D_{n}$ and hence

$$
\begin{equation*}
O_{n} \equiv S C_{n}(\bmod 2) \tag{22}
\end{equation*}
$$

Let $E_{n}$ be the number of even entries in the character table of $S_{n}$. Then

$$
\begin{equation*}
O_{n}+E_{n}=p_{n}^{2} \equiv p_{n}(\bmod 2) \tag{23}
\end{equation*}
$$

where $p_{n}$ is the number of partitions of $n$. Together (22) and (23) imply that

$$
\begin{equation*}
E_{n} \equiv p_{n}-S C_{n}(\bmod 2) \tag{24}
\end{equation*}
$$

But $p_{n}-S C_{n} \equiv 0(\bmod 2)$ because conjugation restricts to a fixed-point-free involution on the set of non-self-conjugate partitions of $n$.

## 4. Tables

The probabilities in Tables 2 and 3 are rounded to the number of digits shown.

TABLE 1. Number of even entries and number of odd entries in the character table of $S_{n}$ for $1 \leq n \leq 76$.
