Abstract. Standard tableaux of skew shape are fundamental objects in enumerative and algebraic combinatorics and no product formula for the number is known. In 2014, Naruse gave a formula (NHLF) as a positive sum over excited diagrams of products of hook-lengths. Subsequently, Morales, Pak, and Panova gave several proofs and generalized it to two $q$-analogues. They also showed, partly algebraically, that the Hillman–Grassl map restricted to skew shapes must be a bijection. We study the problem of circumventing the algebraic part and proving the bijection completely combinatorially. For a skew shape, we define a new set of semi-standard Young tableaux, called the minimal SSYT, that are equinumerous with excited diagrams via a new description of the Hillman–Grassl bijection and a version of excited moves. Lastly, we relate the minimal skew SSYT with the terms of the Okounkov-Olshanski formula (OOF) for counting SYTs of skew shape. Our construction immediately implies that the summands in the NHLF are less than the summands in the OOF.

1 Introduction

Given a partition $\lambda \vdash n$, the number $f^\lambda$ of standard Young tableaux (SYT) of shape $\lambda$ is an important quantity in enumerative, algebraic, and probabilistic combinatorics and is given by the following hook-length formula of Frame-Robinson-Thrall [2] 1954.

\begin{equation}
\tag{1.1}
f^\lambda = \frac{n!}{\prod_{(i,j) \in [\lambda]} h(i,j)},
\end{equation}

where $[\lambda]$ is the Young diagram of $\lambda$ and $h(i,j) = \lambda_i - i + \lambda_j' - j + 1$.

Unlike for straight shapes, there is no such product formula for the number $f_{\lambda/\mu}$ of SYT of skew shape $\lambda/\mu$. There is a determinantal formula for $f_{\lambda/\mu}$ like the Jacobi–Trudi identity, which is efficient but inherently non-positive. There is a classical positive formula for $f_{\lambda/\mu}$ involving the Littlewood–Richardson coefficients $c_{\mu,\nu}^\lambda$, which are themselves hard to compute.

Central to this paper are two other positive formulas for $f_{\lambda/\mu}$ coming from equivariant Schubert calculus or more explicitly from evaluations of factorial Schur functions: the Okounkov–Olshanski formula [14] from 1998 and the Naruse hook-length formula [13] from 2014. We start with the latter since it resembles (1.1).

**Theorem 1.2** (Naruse [13], [10]). For a skew shape $\lambda/\mu$ of size $n$ we have

$$f_{\lambda/\mu} = n! \sum_{S \in E(\lambda/\mu)} \prod_{u \in [\lambda] \setminus S} \frac{1}{h(u)},$$

where $E(\lambda/\mu)$ is the set of excited diagrams of $\lambda/\mu$.

The excited diagrams of shape $\lambda/\mu$, denoted by $E(\lambda/\mu)$, are certain subsets of size $|\mu|$ of the Young diagram of $\lambda$ obtained from the Young diagram of $[\mu]$ by recursively doing a local move $\beta$ [5]. Excited diagrams are in correspondence with certain SSYT of shape $\mu$ that are flagged, i.e. with certain bounds on the entries in each row. The Naruse formula has been actively studied [1, 6, 9, 10].

The other positive formula by Okounkov-Olshanski is also a sum over certain SSYT of shape $\mu$ with entries at most $\ell(\lambda)$ called Okounkov–Olshanski tableaux $OOT(\lambda/\mu)$.

**Theorem 1.3** (Okounkov–Olshanskii [14]). For a skew shape $\lambda/\mu$ of size $n$ we have

$$f_{\lambda/\mu} = \frac{n!}{\prod_{\mu \in [\lambda]} h(u)} \sum_{T \in OOT(\lambda/\mu)} \prod_{(i,j) \in [\mu]} (\lambda_{\ell+1-T(i,j)} - i + j).$$

In [12], Morales–Zhu did a similar study of (OOF) as Morales–Pak–Panova did in [9, 10] for (NHLF). In particular, they gave in [12, Cor. 5.7] a reformulation of (OOF) in terms of the following flagged tableaux: SSYT of shape $\lambda/\mu$ with entries in row $i$ at most $i - 1$, whose set we denote by $SF(\lambda/\mu)$.

A new formulation of Naruse’s formula: A natural question, which is the start of our investigation, is to also find a reformulation of (NHLF) in terms of some SSYT of skew shape $\lambda/\mu$. We define the set $SSYT_{\text{min}}(\lambda/\mu)$ of minimal skew SSYT obtained from the minimum SSYT, $T_0$ of shape $\lambda/\mu$ with entries $\{0, 1, \ldots, \lambda_i - \mu_i' - 1\}$ by recursively doing local moves $\delta$. Our first result is a bijection $\Phi$ between excited diagrams and tableaux $SSYT_{\text{min}}(\lambda/\mu)$ that intertwines with the respective local moves $\beta$ and $\delta$, respectively.

**Theorem 1.4.** For a skew shape $\lambda/\mu$ the map $\Phi : E(\lambda/\mu) \to SSYT_{\text{min}}(\lambda/\mu)$ is a bijection that intertwines with the respective local moves, that is $\Phi \circ \beta = \delta \circ \Phi$. 
As a corollary, we obtain a new reformulation of (NHLF). Let \((\theta_1, \ldots, \theta_k)\) be the Lascoux–Pragacz decomposition of the shape \(\lambda/\mu\) into border strips.

**Theorem 1.5** (minimal SSYT version of (NHLF)). For a skew shape \(\lambda/\mu\) of size \(n\) we have

\[
f_{\lambda/\mu} = \frac{n!}{\prod_{u \in [\lambda]} h(u)} \sum_{T \in \text{SSYT}_{\text{min}}(\lambda/\mu)} \prod_{(i, j) \in [\mu]} h(i + \alpha, j + \alpha),
\]

where \(\alpha\) is the number strips \(\theta_k\) such that \(\overline{T}(\theta_k(j)) > \mu'_j - i\) and \(\overline{T} = T - T_0\).

We give an explicit non-recursive description of the tableaux in \(\text{SSYT}_{\text{min}}(\lambda/\mu)\) (Theorem 2.6) that immediately shows they are a subset of the skew flagged tableaux \(\mathcal{SF}(\lambda/\mu)\) (see Lemma 3.4). As a corollary, we obtain that the Okounkov–Olshanski formula has at least as many terms as the Naruse formula and characterize the skew shapes where equality is attained. We denote the number of terms of each formula by \(\text{ED}(\lambda)\) and \(\text{OOT}(\lambda/\mu)\), respectively.

**Theorem 1.6.** For a connected skew shape \(\lambda/\mu\) with \(d = \ell(\lambda)\) and \(r = \max\{i \mid \mu_1 = \mu_i\}\), we have that \(\text{ED}(\lambda/\mu) \leq \text{OOT}(\lambda/\mu)\) with equality if and only if \(\lambda_d \geq \mu_r + d - r\).

**Relation with the Hillman–Grassl correspondence:** The hook-length formula (1.1) has a \(q\)-analogue by Littlewood that is a special case of Stanley’s hook-content formula for the generating series of SSYT of shape \(\lambda\).

**Theorem 1.7** (Littlewood). For a partition \(\lambda\) we have

\[
s_\lambda(1, q, q^2, \ldots) = q^{\sum (i-1)\lambda_i} \prod_{u \in \lambda} \frac{1}{1 - q^{h(u)}}.
\]

This \(q\)-analogue has a bijective proof by Hillman–Grassl via the correspondence \(\text{HG}(\cdot)\) between reverse plane partitions of shape \(\lambda\) and arrays of nonnegative integers of shape \(\lambda\). This correspondence is related to the famous RSK correspondence (see [3, 10]) and has recent connections to quiver representations [4].

In [10], Morales–Pak–Panova gave a \(q\)-analogue of (NHLF) for the generating functions of SSYT of skew shape \(\lambda/\mu\).

**Theorem 1.8** (Morales–Pak–Panova [10]). For a skew shape \(\lambda/\mu\) we have

\[
s_{\lambda/\mu}(1, q, q^2, \ldots) = \sum_{D \in \mathcal{E}(\lambda/\mu)} \prod_{(i, j) \in D} \frac{q^{\lambda'_j - i}}{1 - q^{h(i, j)}}.
\]
Interestingly, this identity corresponds to restricting the Hillman–Grassl bijection to SSYT of shape $\lambda/\mu$ [10]. The resulting arrays $A^*(\lambda/\mu)$ have support on the complement of excited diagrams and with certain forced nonzero entries on broken diagonals. The proof of this connection with the Hillman–Grassl map $HG(\cdot)$ is partly algebraic and remained mysterious. Our next results elucidate on this.

First, we show that the bijection between minimal tableaux and excited diagrams coincides with the Hillman–Grassl map.

**Theorem 1.9.** The map $\Phi$ is equivalent to the inverse Hillman–Grassl map $HG^{-1}$ on the arrays $A^*(\lambda/\mu)$. That is for $A_D$ in $A^*(\lambda/\mu)$ we have $HG^{-1}(A_D) = \Phi(D)$.

As a corollary, we obtain a bijective proof of part of (1.4) by taking the leading terms of each summand on the right-hand-side.

**Corollary 1.10.** For a shape $\lambda/\mu$ we have
$$
\sum_{T \in \text{SSYT}_{\text{min}}(\lambda/\mu)} q^{|T|} = \sum_{D \in \mathcal{E}(\lambda/\mu)} q^{\sum_{(i,j) \in D}(\lambda'_j - i)}.
$$

We also give a fully bijective proof of (1.4) for the case of border strips. The details of this last result and full version of this abstract will appear in [11].

## 2 Minimal semistandard tableaux of shape $\lambda/\mu$

### 2.1 Excited diagram and broken diagonals

Given a subset $D$ of $[\lambda]$, a cell $(i,j)$ of $D$ is active if the cells $(i+1,j), (i,j+1), (i+1,j+1)$ are not in $D$ but are in $[\lambda]$. Given an active cell $(i,j)$ of $D$, let $\beta_{(i,j)} : D \to D'$ be the map that replaces cell $(i,j)$ in $D$ by $(i+1,j+1)$. We call such $\beta_{(i,j)}$ an excited move. An excited diagram of $\lambda/\mu$ is a set of $|\mu|$ cells obtained from $[\mu] \subseteq [\lambda]$ by applying excited moves. We let $\mathcal{E}(\lambda/\mu)$ be the set of excited diagrams of $\lambda/\mu$ (see Figure 2a). These diagrams were introduced by Ikeda–Naruse in [5].

Each excited diagram $D$ is associated with the broken diagonals $\text{Br}(D)$, which are obtained from the sub-diagonals of $\lambda/\mu$ by applying excited moves. For $\beta_{(i,j)} : D \to D'$, then $\text{Br}(D') = \text{Br}(D) \setminus \{(i+1,j+1)\} \cup \{(i+1,j)\}$ (see Figure 2a).

### 2.2 Lascoux–Pragacz and Kreiman decomposition of $\lambda/\mu$

We review two different decompositions of a Young diagram of shape $\lambda/\mu$ into strips (connected skew shapes with no $2 \times 2$ box), see Figure 1a.

The **Lascoux–Pragacz decomposition** of $\lambda/\mu$ is a tuple of non-intersecting lattice paths $(\theta_1, \ldots, \theta_k)$, where $\theta_1$ is the outer border strip of $\lambda$, which starts at the southwest corner of $[\lambda/\mu]$ and ends at the northeast corner of $[\lambda/\mu]$ [8]. Then $\theta_2$ is the outer border strip of $\lambda \setminus \theta_1$ and each $\theta_i$ is the outer border strip of $\lambda \setminus \theta_1 \setminus \cdots \setminus \theta_{i-1}$. We assume each strip
\( \theta_i \) starts at the left or bottom of \([\lambda/\mu]\) and ends at the right or top of \([\lambda/\mu]\). Given a skew shape \( \lambda/\mu \), and its Lascoux-Pragacz decompositions \((\theta_1, \ldots, \theta_k)\), denote \( f(\theta_r) \) the row number of the top most element of \( \theta_r \). We define the \( \theta_i \)-height of row \( i \), denoted as \( \text{ht}_{\theta_i}(i) \) to be \( i - f(\theta_r) \). For example, in Figure 1a, the height of the element \((7, 2)\) in \( \theta_1 \) is 6 whereas the height of \((4, 1)\) in \( \theta_4 \) is 1.

The Kreiman decomposition of \( \lambda/\mu \) is a tuple \((\gamma_1, \ldots, \gamma_k)\) of non-intersecting lattice paths with support \([\lambda/\mu]\), where each \( \gamma_i \) begins at the southwest corner and ends at northeast corner \([7]\) (see Figure 1a). We denote \( \epsilon_i \) the distance between \( \gamma_1 \) and \( \gamma_i \). The support of such paths are the complement of excited diagrams \([7, \S 5, \S 6]\). If an excited diagram \( D \) corresponds to the tuple \((\gamma'_1, \ldots, \gamma'_k)\), we denote by \( \gamma_i(D) = \gamma'_i \), the path obtained from \( \gamma_i \) after applying the corresponding ladder moves to the excited moves where \([\mu]\) is obtained from \( D \) (see Figure 2a).

**Lemma 2.1.** Let \((\gamma_1, \ldots, \gamma_k)\) and \((\theta_1, \ldots, \theta_k)\) be the Kreiman and Lascoux-Pragacz decomposition of shape \( \lambda/\mu \). For each \( i \in \{1, \ldots, k\} \), let \( \gamma_i : (f_i, g_i) \rightarrow (e_i, d_i) \) and \( \theta_i : (s_i, t_i) \rightarrow (u_i, v_i) \). Then \( g_i - t_i = \epsilon_i \), i.e. the column difference of the starting point of \( \gamma_i \) and \( \theta_i \) is \( \epsilon_i \).

### 2.3 Minimal skew Semistandard Young Tableaux

The minimal skew SSYT are obtained from the minimum SSYT \( T_0 \) by applying a sequence of excited moves \( \delta \), defined as follows (see Figure 1b). Let \( \lambda/\mu \) be a skew partition and \((\theta_1, \ldots, \theta_k)\) be its Lascoux-Pragacz decomposition. Given a strip \( \theta_k \) and column \( j \), let \( \theta_k(j) \) be the \( j \)th column segment of \( \theta_k \). Let \((i, j)\) be the top-most cell and \((i', j)\) be the bottom-most cell of \( \theta_k(j) \) (which may agree if the column has size one).

**Definition 2.2** (excited move \( \delta \)). The column \( \theta_k(j) \) of \( T \) in SSYT \((\lambda/\mu)\) is active if

(i) \( T(i, j) < \text{ht}_{\theta_k}(i) \),

(ii) \( T(i, j) < T(i, j + 1) \) and \( T(i', j) < T(i' + 1, j) + 1 \).

Given an active column \( \theta_k(j) \) of \( T \), the excited move \( \delta \) adds one to each entry in the column segment \( \theta_k(j) \) and \( T' := \delta_{(k,j)}(T) \) be the tableau obtained from \( T \) by the move \( \delta \).
We define a bijection between $E(\lambda/\mu)$ and $SSYT_{\min}(\lambda/\mu)$ denoted $\Phi : E(\lambda/\mu) \rightarrow SSYT(\lambda/\mu)$, which commutes with the excited moves in $E(\lambda/\mu)$ and $SSYT_{\min}(\lambda/\mu)$.

**Definition 2.3.** Given $D \in E(\lambda/\mu)$, let $(\gamma_1(D), \ldots, \gamma_k(D))$ and $(\theta_1, \ldots, \theta_k)$ be its Kreiman and Lascoux-Pragacz decomposition into paths and $Br(D)$ be its set of broken diagonals. Let $b_j$ be the number of broken diagonals on the $j$th column of $\gamma_i(D)$. For each $\gamma_i(D)$ and $\theta_i$, do the following procedure starting from the left most column of each path to obtain $T := \Phi(D)$:

1. Denote the bottom-most element of the $j$th column of $\theta_i$ as $(s_j, t_j)$. Let
   \[
   T(s_j, t_j) = \begin{cases} 
   b_j & \text{if } j = 1, \\
   T(s_j, t_j - 1) + b_j & \text{if } j > 1.
   \end{cases}
   \]
2. Fill the rest of the $j$th column of $\theta_i$ so that each entry differs by $1$.

The proof that $\Phi$ is well defined can be found in the full version [11].

**Example 2.4.** Let $D \in E(\lambda/\mu)$ be the excited diagram shown in Figure 1c. We apply the correspondence to obtain $T = \Phi(D)$. The first column of $\gamma_1(D)$ has three broken diagonals, so $T(5,1) = 3$. The second column of $\gamma_1(D)$ has no broken diagonals, so $T(5,2) = 3$, then the rest of the column of $\theta_1$ is filled with each entry differing by $1$ to maintain column strictness. We continue the algorithm to obtain the final tableau $T$ of skew shape $\lambda/\mu$.

For the Lascoux–Pragacz decomposition of $[\lambda/\mu]$ and the Kreiman paths $(\gamma_1, \ldots, \gamma_k)$ corresponding to an excited diagram $D$, we denote by $\text{col}_{\lambda/\mu}(\theta_i, n)$ and $\text{col}_{\lambda/\mu}(\gamma_i, n)$ the column on $\lambda/\mu$ where the $n$th column of $\theta_i$ and $\gamma_i$ is, respectively.

**Lemma 2.5.** Given an excited diagram $D \in E(\lambda/\mu)$ and an active cell $u = (a, b)$ of $D$ we have
\[
\Phi(\beta_u(D)) = \delta_{f(i)}(\Phi(D)),
\]
where $f(a, b) = (i; \mu(a, b))$, $i$ is the index of the Kreiman path $\gamma_i(D)$ modified by $\beta(a, b)$, and $\mu(a, b)$ is the column of the original cell in $\mu$ where $(a, b)$ came from.

**Proof.** The excited move $\beta_{(a,b)}$ corresponds to a ladder move on $\gamma_i(D) \rightarrow \gamma_i(D')$, for some $i$ and a broken diagonal shift from $(a+1, b+1)$ to $(a+1, b)$. Let $g_i$ and $t_i$ be the starting column of $\gamma_i(D)$ and $\theta_i$, respectively. Suppose $(a+1, b)$ is in the $j$th column of the path $\gamma_i(D)$. Then the excited move $\beta_{(a,b)}$ shifts a broken diagonal to the $j$-th column of $\gamma_i(D')$, where $j = b - g_i + 1$. The $j$-th column of $\gamma_i(D)$ corresponds to the $j$-th column of $\theta_i$, which corresponds to column $t_i + j - 1$ of shape $\lambda/\mu$. By Lemma 2.1 we know that $g_i - t_i = \epsilon_i$. Thus we have that
\[
\text{col}_{\lambda/\mu}(\theta_i, j) = t_i + j - 1 = (g_i - \epsilon_i) + (b - g_i + 1) - 1 = b - \epsilon_i.
\]
We know that $\epsilon_i$ is also the number of times $(a, b)$ has been excited, which is $b - \mu(a, b)$. Therefore we have that $\text{col}_{\lambda/\mu}(\theta_i, j) = \mu(a, b)$. This shows that $\Phi(\beta_u(D))$ has increments of $1$ on $\theta_i$ at column $\mu(a, b)$ compared to $\Phi(D)$). This is equivalent to what the move $\delta_{(i;\mu(a,b))}$ does on $\Phi(D)$. Thus $\Phi(\beta_u(D)) = \delta_{(i;\mu(a,b))}(\Phi(D))$, as desired. \qed
In this section we use the bijection $\Phi$ to reformulate the Naruse hook formula (NHLF) in terms of minimal SSYT. We need the following description of the inverse of $\Phi$.

**Proof sketch of Theorem 1.4.** By Lemma 2.5, $\Phi$ intertwines the excited moves $\beta$ and $\delta$. One can check that $\Phi$ is injective. Note that $\Phi([\mu]) = T_0$. Given any excited diagram $D$ in $\mathcal{E}(\lambda/\mu)$, there exists a sequence $\beta_1, \ldots, \beta_m$ of excited moves such that $D = \beta_m \circ \cdots \circ \beta_1([\mu])$. Iterating Lemma 2.5 gives that $\Phi(D) = \delta_m \circ \cdots \circ \delta_1(T_0)$.

Thus $\Phi(D)$ is in SSYT$_{\min}(\lambda/\mu)$ and so $\Phi(\mathcal{E}(\lambda/\mu)) \subseteq$ SSYT$_{\min}(\lambda/\mu)$. It remains to show that $\Phi(D)$ is surjective. Given $T$ in SSYT$_{\min}(\lambda/\mu)$, there exists a sequence of $\delta_1, \ldots, \delta_k$ of excited moves such that $\delta_k \circ \cdots \circ \delta_1(T_0) = T$. Again, iterating Lemma 2.5 we have that for $D' = \beta_k \circ \cdots \circ \beta_1([\mu])$, one obtains $\Phi(D') = T$, as desired. \qed

There is the following non-recursive description of the minimal SSYT. This new characterization will be related to the Okounkov–Olshanski tableaux in the next section. We omit the details of the proof.

**Theorem 2.6.** A SSYT $T$ of shape $\lambda/\mu$ is in SSYT$_{\min}(\lambda/\mu)$ if and only if

(i) For each $(i_r, j_r)$ in $\theta_r$, $T(i_r, j_r) \leq \text{ht}_{\theta_r}(i_r)$

(ii) For any $(i_r, j_r)$ and $(i_r + 1, j_r)$ in $\theta_r$, $T(i_r + 1, j_r) - T(i_r, j_r) = 1$.

In other words, the set SSYT$_{\min}(\lambda/\mu)$ consists of SSYT of shape $\lambda/\mu$ where the values along each path $\theta_r$ are bounded by the height $\text{ht}_{\theta_r}$ and the values along entries in the same column of a strip $\theta_r$ differ by one.

## 3 Reformulation of (NHLF) and comparison with (OOF)

In this section we use the bijection $\Phi$ between minimal SSYT and excited diagrams of shape $\lambda/\mu$ to reformulate the Naruse hook formula (NHLF) in terms of minimal SSYT. We need the following description of the inverse of $\Phi$. 

![Figure 2:](a) The $\mathcal{E}(55332/22)$, their corresponding $\gamma_i(D)$ (in blue) and broken diagonals (in red). (b) The SSYT$_{\min}(55332/22)$ with the active columns colored in yellow and red.)
Lemma 3.1 (Inverse of $\Phi$). Let $D \in \mathcal{E}(\lambda/\mu)$ and recall $\overline{T} = T - T_0$, where $T_0$ is the minimum skew SSYT and $T = \Phi(D)$. Then

$$D = \{(i + \alpha, j + \alpha) \mid (i, j) \in [\mu]\},$$

where $\alpha$ is the number of strips $\theta_k$ such that $\overline{T}(\theta_k(j)) > \mu'_j - i$.

Proof of Theorem 1.5. The result follows by combining the excited diagram formulation (NHLF) of Naruse’s formula and the description of inverse of $\Phi$ from Lemma 3.1.

Example 3.2. For the shape $\lambda/\mu = 55332/22$, from each of its minimal tableaux in Figure 2b we find $\overline{T}$:

Next, for each $\overline{T}$ and $(i, j)$ in $\mu = [22]$, we find $\alpha$. Putting everything together using (1.2) gives

$$f^{\lambda/\mu} = \frac{14!}{98^2 76^6 52^4 3^2 2^4} (h(1, 1)h(1, 2)h(2, 1)h(2, 2) + h(1, 1)h(1, 2)h(2, 1)h(2+1, 2+1)$$

$$+ h(1, 1)h(1+1, 2+1)h(2, 1)h(2+1, 2+1) + h(1, 1)h(1, 2)h(2+1, 1+1)h(2+1, 2+1) + h(1, 1)h(1+1, 2+1)h(2+1, 1+1)h(2+1, 2+1) + h(1+1, 1+1)h(1+1, 2+1)h(2+1, 2+1)).$$

In the rest of this section we use the explicit non-recursive description of the skew minimal tableaux in $\text{SSYT}_{\min}(\lambda/\mu)$ of Theorem 2.6 to relate the number $\text{ED}(\lambda/\mu)$ of terms of (NHLF) and the number $\text{OOT}(\lambda/\mu)$ of terms of (OOF).

Theorem 3.3. For a skew shape $\lambda/\mu$ we have that $\text{ED}(\lambda/\mu) \leq \text{OOT}(\lambda/\mu)$. 

---

Figure 3: (a) Example of bijection $\Phi^{-1}$ between a minimal SSYT and excited diagrams for the shape $\lambda/\mu = 55552/21$. (b) Illustration of skew shapes $\lambda/\mu$ and their Lascoux–Pragacz decomposition with $\lambda_d \geq \mu_r + d - r$ where $\text{ED}(\lambda/\mu) = \text{OOT}(\lambda/\mu)$.
The proof follows immediately from the following lemma.

**Lemma 3.4.** For a skew shape $\lambda/\mu$ we have that $\text{SSYT}_\text{min}(\lambda/\mu) \subseteq \mathcal{SF}(\lambda/\mu)$.

**Proof.** Let $T$ be a tableau in $\text{SSYT}_\text{min}(\lambda/\mu)$. By Condition (i) in Theorem 2.6, we have that for $(i,j)$ in $\theta_r$, $T(i,j) \leq \text{ht}_{\theta_r}(i)$. By definition of the height, we have that $\text{ht}_{\theta_r}(i) \leq i - 1$. Thus $T$ is a flagged tableau in $\mathcal{SF}(\lambda/\mu)$.

**Theorem 1.6** characterizes the skew shapes where the Naruse hook-length formula and the Okounkov–Olshanski formula have the same number of terms.

**Proof sketch of Theorem 1.6.** The inequality $\text{ED}(\lambda/\mu) \leq \text{OOT}(\lambda/\mu)$ follows from Theorem 3.3. By Lemma 3.4 we have that equality occurs if and only if all the flagged tableaux in $\mathcal{SF}(\lambda/\mu)$ are minimal. First, define the maximal tableau $T \in \mathcal{SF}(\lambda/\mu)$ as $T(i,j) = i - 1$ for $(i,j) \in [\lambda/\mu]$, and let $(\theta_1, \ldots, \theta_k)$ be the Lascoux-Pragacz decomposition of $\lambda/\mu$.

By the height condition in the definition of minimal tableaux (Condition (i) in Theorem 2.6), it follows that all border strips $\theta_k$ reach the top row. The border strips $\theta_k$ are entirely horizontal in the first $\mu_1$ columns of $\lambda/\mu$ and we have $d - r$ of them starting in the first $\mu_1$ columns. Thus $\lambda_d \geq \mu_1$. Also, since these border strips reach the top row, they must all cross the diagonal starting at $(r, \mu_r)$ and thus this diagonal extends to the last row of the shape, so $\lambda_d \geq \mu_r + d - r$, which proves the forward direction. See Figure 3b.

For the other direction, if $\lambda_d \geq \mu_r + d - r$, then it is easy to see that all border strips $\theta_i$ reach the top row and they are horizontal in the first $\mu_1$ columns. The tableaux in $\mathcal{SF}(\lambda/\mu)$ consisting of the columns past $\mu_1$ are of straight shape, and one can show the entries in row $i$ are $i - 1$. For the first $\mu_1$ columns, since all border strips are horizontal, there are no further restrictions coming from the minimal tableaux. Thus $\text{SSYT}_\text{min}(\lambda/\mu) = \mathcal{SF}(\lambda/\mu)$, as desired. \qed

For shapes where $\text{ED}(\lambda/\mu) = \text{OOT}(\lambda/\mu)$, this number is given by the hook-content formula. We omit the proof.

**Corollary 3.5.** For a connected skew shape $\lambda/\mu$ satisfying $\lambda_d \geq \mu_r + d - r$ where $d = \ell(\lambda)$ and $r = \max\{i \mid \mu_1 = \mu_i\}$, we have that $\text{ED}(\lambda/\mu) = \text{OOT}(\lambda/\mu) = s_\mu(1^{d-r})$.

### 4 The Hillman–Grassl correspondence and the map $\Phi$

In this section, we sketch the proof of Theorem 1.9.
4.1 Background on Hillman–Grassl

We denote by \( HG(\cdot) \) the Hillman–Grassl bijection between reverse plane partitions in \( \text{RPP}(\lambda) \) ranked by size and integer arrays of shape \( \lambda \) ranked by hook weight. That is, if \( HG : \pi \mapsto A \) then \(|\pi| = \sum_{u \in \lambda} h(u) \cdot A_u\). We follow the definition of \( HG(\cdot) \) in [15, §7.22]. This bijection also implies (1.3) as a corollary.

**Definition 4.1 (Hillman–Grassl correspondence).** The correspondence is obtained via a sequence of pairs \((\pi_0, A_0) := (\pi, 0), (\pi_1, A_1) \ldots, (\pi_k, A_k) := (0, HG(\pi))\) where each \(\pi_i\) is a reverse plane partition and \(A_i\) is an array of nonnegative integers of shape \(\lambda\) obtained recursively as follows:

(i) start at the SW most nonzero cell of \(\pi_i\),

(ii) traverse a NE path: from cell \((a, b)\), if \((\pi_i)_{a,b} = (\pi_i)_{a-1,b}\) then the path moves North, otherwise the path moves East.

(iii) Terminate when this is no longer possible.

Let \(u_i = (c, d)\) where \(d\) is the column where the path starts and \(c\) is the row where it ends. Note that \(|\pi_i| - |\pi_{i-1}| = h(u_i)\). We obtain the array \(A_{i+1}\) from \(A_i\) by adding one to cell \(u_i\). We continue until \(\pi_k\) as only zero entries. We let \(A_k = HG(\pi)\).

We extend \(HG\) to \(\text{SSYT}(\lambda/\mu)\) by viewing each skew SSYT \(T\) as a plane partition of shape \(\lambda\) with zero entries in \([\mu]\).

For any excited diagram \(D \in E(\lambda/\mu)\), denote by \(A_D\) the 0-1 array of shape \(\lambda\) with support on the broken diagonals \(\text{Br}(D)\) of \(D\) and let \(\mathcal{A}^*(\lambda/\mu) = \{A_D \mid D \in E(\lambda/\mu)\}\). Let \(\mathcal{A}_D^*\) be the set of arrays \(A\) of nonnegative integers of shape \(\lambda\) with support contained in \([\lambda]\setminus D\) and positive entries \(A_{i,j} > 0\) if \((A_D)_{i,j} = 1\).

**Theorem 4.2 ([10, Thm. 7.7]).** The (restricted) Hillman–Grassl map \(HG\) is a bijection

\[HG : \text{SSYT}(\lambda/\mu) \rightarrow \bigcup_{D \in E(\lambda/\mu)} \mathcal{A}_D^*.\]

This property combined with the correspondence between RPPs and SSYTs of straight shape yields (1.4) as a corollary (see [10, Sec. 7.1]). The proof of this result is partly algebraic and the authors of [10] asked for a fully bijective proof. We make progress on this question by (i) giving a combinatorial proof for border strips \(\lambda/\mu\), and (ii) characterizing what is the image of \(\text{SSYT}_{\text{min}}(\lambda/\mu)\). We sketch the latter in the next section and the former is in [11].

4.2 Hillman–Grassl on minimal skew SSYT

In this section we give the necessary lemmas to prove Theorem 1.9. Fix a skew shape \(\lambda/\mu\) with Lascoux–Pragacz decomposition \((\theta_1, \ldots, \theta_k)\).
Let $A_{\gamma_i(D)}$ be the a subarray of $A_D$ of shape $\lambda \setminus \cup_{j=1}^{i-1} \gamma_j(D)$ with support on the broken diagonal of $\gamma_i(D)$. We define the sum $A_{\gamma_i(D)} + A_{\gamma_i+1(D)}$ as an array of shape $A_{\gamma_i(D)}$ with supports on the broken diagonals of $\gamma_i(D)$ and $\gamma_i+1(D)$. In other words, it is the entry-wise sum of the arrays where alignment of $A_{\gamma_i(D)}$ and $A_{\gamma_i+1(D)}$ corresponds to the original $A_D$ (see Figure 4a).

Similarly, let $T_{\theta_i}$ be a SSYT of shape $\lambda \setminus \cup_{j=1}^{i-1} \theta_j(D)$ with tableau entries in $\theta_i$. We define the $T_{\theta_i} \cup T_{\theta_{i+1}}$ to be the tableaux of shape $T_{\theta_i}$ with entries of both $\theta_i$ and $\theta_{i+1}$.

The first lemma is a variation of Theorem 1.9 restricted to the individual $\gamma_i$ and $\theta_i$ (see Figure 4a).

**Lemma 4.3.** Let $D \in \mathcal{E}(\lambda/\mu)$ and $T = \Phi(D) \in \text{SSYT}_{\min}(\lambda/\mu)$. Then for $i = 1, \ldots, k$ we have that $HG(T_{\theta_i}) = A_{\gamma_i(D)}$.

In order to show Theorem 1.9, we need the following additivity results (see Section 4.2). We define the sum of arrays $HG(T_{\theta_i})$ and $HG(T_{\theta_{i+1}})$ similarly to the sum of $A_{\gamma_i(D)}$ and $A_{\gamma_i+1(D)}$. We omit the technical proof by induction.

**Lemma 4.4.** We have that $\sum_{i=1}^{k} HG(T_{\theta_i}) = HG(T_{\theta_1 \cup \cdots \cup \theta_k})$.

**Proof sketch of Theorem 1.9.** We have that $T_{\theta_1 \cup \cdots \cup \theta_k} = \Phi(D)$. We obtain the desired identity $HG(\Phi(D)) = \sum_{i=1}^{k} A_{\gamma_i(D)} = A_D$ by Lemma 4.3 and Lemma 4.4. \qed
