Communicated by F. Brezzi

This paper focuses on a three-dimensional phenomenological model for the isothermal evolution of a polycrystalline shape memory alloy. The model, originally proposed by Auricchio, Taylor, and Lubliner in 1997, is thermodynamically consistent and reproduces the crucial martensitic reorientation effect as well as the tension-compression asymmetric behavior of the material. We prove the existence of a weak solution of the corresponding quasistatic evolution problem by passing to the limit within a time-discretization procedure.

Keywords: Shape memory alloys; quasistatic evolution; existence; time-discretization.

AMS Subject Classification: 74C05, 35K55

1. Introduction

Shape memory alloys (SMAs) are metallic alloys showing an amazing capability of recovering large deformations (see Frémond24). In the isothermal high-temperature regime, SMAs exhibit the so-called superplastic behavior (also called pseudoplastic or even pseudoplastic): deformations up to 8% are fully recovered upon unloading (note that ordinary steels plasticize around 1%). By allowing temperature changes, SMAs show also the celebrated shape memory effect: permanently deformed specimens can be forced back into the original undeformed configuration by a purely thermal treatment (heating).

At the microscopic level, SMAs experience abrupt and diffusionless stress- and temperature-driven phase transitions between different configuration of the metallic lattices. In particular, a highly symmetric crystallographic phase called austenite
(mostly cubic, predominant at higher temperatures) transforms into less symmetric phases called martensites (different variants due to symmetry breaking, energetically favorable at lower temperatures). By cooling down at zero stress a fully austenitic specimen below some critical temperature, the material develops a finely structured martensitic phase. Roughly speaking, martensitic variants combine in twins in order to minimize macroscopic motions. This structured phase is called multi-variant martensite (or twinned, non-oriented, self-accommodated). By keeping the temperature constant and applying an external stress, one specific martensitic variant turns out to be mechanically favorable and both the austenite and/or the multi-variant martensite progressively transform into a single-variant martensite (detwinned, oriented). This fact gives rise to a macroscopic deformation due to the specific asymmetry of the selected single martensitic variant. The latter phase transformation is of the first order (no latent heat) and the single-variant martensite (product phase) transforms back to austenite and/or multi-variant martensite (parent phase) upon unloading.

The special thermomechanical behavior of SMAs is at the basis of a variety of innovative applications from Aerospace, to Earthquake, to Biomedical Engineering and has been the subject of an intense research within the Materials Engineering community in recent years (see Duerig et al.\textsuperscript{17,18}). Indeed, SMA behavior has been investigated at all scales (microscopic, mesoscopic with volume fractions, macroscopic) by means of a full menagerie of modeling perspectives (see Roubíček\textsuperscript{50}) and with ambitions for different ranges of applicability (from single crystals to commercial devices). A collection of different \textit{macroscopic/phenomenological} modeling options and some corresponding discussion is to be found in the papers by Falk,\textsuperscript{20} Falk and Konopka,\textsuperscript{21} Frémond,\textsuperscript{23} Govindjee and Miehe,\textsuperscript{25} Helm and Haupt,\textsuperscript{27} Lagoudas et al.,\textsuperscript{32} Popov and Lagoudas,\textsuperscript{45} Levitas,\textsuperscript{33} Peultier \textit{et al.},\textsuperscript{43} Raniecki and Lexcellent,\textsuperscript{46} Reese and Christ,\textsuperscript{47} Thamburaja and Anand,\textsuperscript{51} Thiebaud \textit{et al.},\textsuperscript{52}; see also the survey by Roubíček.\textsuperscript{50}

We are here concerned with a 3D model of the isothermal, superelastic behavior of polycrystalline SMAs specimens originally advanced by Auricchio, Taylor and Lubliner\textsuperscript{11} (ATL model in the following). The temperature of the body is assumed to be fixed (and suitably high) throughout and stress-induced reversible phase transformations between parent and product phases are considered. The main focus of the ATL model is toward a description of the \textit{martensitic reorientation} phenomenon, that is the inelastic behavior determined from the progressive stress-driven reorientation of fully-oriented, single-variant martensites. In particular, the inelastic deformation $\varepsilon^{tr}$ due to phase transformation is assumed in the form

$$
\varepsilon^{tr} = \xi \frac{\partial F(\sigma)}{\partial \sigma},
$$

(1.1)

where $F$ is the so-called Drucker–Prager function of the stress $\sigma$. Note that the specific choice of $F$ will take into account the \textit{asymmetric response} of the material in tension and compression. In the spirit of generalized plasticity models.\textsuperscript{34}
the inelastic description of the material from (1.1) is complemented by directly prescribing a rate-independent evolution law for the single-variant martensite volume fraction $\xi$.

The ATL model is *scalar*: the actual phase structure of the material is completely encoded in the scalar internal variable $\xi$ and the martensitic reorientation phenomenon is described in (1.1) by assuming *a priori* that the relevant direction of $\varepsilon^{\text{tr}}$ is directly given by the stress $\sigma$ via $F$. This is of course a crude simplification with respect to the truly tensorial nature of superelasticity in polycrystals, some results in the direction of coping with a tensorial internal variable may be found in the papers by Auricchio *et al.*, 4–8 Krejčí and Stefanelli, 29,30 Still, the simplicity of the ATL model, its robustness with respect to discretizations (see Auricchio and Stefanelli), and its ability to capture experimental evidence are remarkably promising. The first mathematical treatment of the ATL model is given by Auricchio and Stefanelli where the authors focus on the constitutive material equation and present an effective discretization algorithm. In particular, approximations are obtained by adapting to the current context of the well-known return map algorithm in plasticity and sharp and explicit error bounds as well as numerical experiments are presented. The analysis of Ref. 9 has been extended and combined with a well-posedness theory for the related quasistatic one-dimensional equilibrium problem in Ref. 10. In particular, time-discrete schemes with sharp error bounds have been obtained for both the stress and the displacement-driven case.

As the ATL model is restricted to the isothermal regime, the description of the shape memory effect is clearly out of reach. We shall however stress that the isothermal approximation often shows good accordance with experiments in real superelastic situations. This is particularly the case when the changes of the loading are comparably slow and the SMA body is thin in at least one direction. In this case one can assume that the heat produced by the dissipative reorientation mechanism is (almost) immediately transported to the surrounding environment. Even in terms of energetics, experimental evidence shows that the influence of (irreversible) internal dissipation is very small compared with the (reversible) thermomechanical energy dynamics along loading-unloading cycles (see Peyroux *et al.*).

The main result of this paper is the proof of the existence of a weak solution of the quasistatic equilibrium problem in three-space dimensions. The strategy of the proof is based on a time-discretization technique and the bottleneck of all the analysis is clearly the treatment of (1.1) for passage to limits in this product necessarily requires strong convergences. We achieve this by compactness and direct Cauchy arguments and, in particular, by including a deformation-gradient term in the momentum balance equation. The key point of the convergence proof for the time-discretization is a dissipativity estimate. Despite the *failure of monotonicity* and the *nonsmoothness* in (1.1), the specific form of the evolution law for $\xi$ allows for a crucial bound on time derivatives (see (5.7) below).
We shall stress that, the ATL model is associative in the sense of classical plasticity theory (see Han and Reddy[26]). In particular, the constitutive equation for the material can be expressed as a generalized balance between conservative and dissipative actions driven by potentials (see Sec. 2.6) and we are hence dealing with a so-called rate-independent system (see Mielke et al.,[39] the survey by Mielke[35] and the references therein). On the other hand, our existence result cannot be directly reduced to the by now classical theory of energetic solvability of such systems initiated by Mielke and Theil[38] and later developed by many Authors (see Dal Maso et al.,[16] Francfort and Mielke,[22] Kružík et al.,[31] Mielke and Roubíček,[36] Mielke et al.[37] and Roubíček[39] among others) for the involved potentials lack the required smoothness. This particularly motivates our ad hoc analysis.

2. The ATL Model

We devote this section to introduce some notation and recall the basic features of the ATL model from Ref. 11. Note that additional material on the ATL model can be found in the papers by Auricchio, 2 Auricchio and Lubliner, 3 and Lubliner and Auricchio,[34] where the interested reader is referred for remarks, outcome of numerical experiments, and comments on validation.

2.1. Tensors

Let $\mathbb{R}_{\text{sym}}^{3 \times 3}$ denote the space of symmetric $3 \times 3$ tensors endowed with the natural scalar product $A : B = \text{tr}(AB') = A_{ij}B_{ij}$ (summation convention) and the norm $|A|^2 = A : A$. We decompose $\mathbb{R}_{\text{sym}}^{3 \times 3} = \mathbb{R}_{\text{dev}}^{3 \times 3} \oplus \mathbb{R}_{12}$ where $\mathbb{R}_{\text{dev}}^{3 \times 3}$ is the deviatoric subspace of $\mathbb{R}_{\text{sym}}^{3 \times 3}$ defined by $\text{tr}A = 0$ and $I_2$ is the identity 2-tensor. For all $u \in H^1_\text{loc} (\mathbb{R}^3 ; \mathbb{R}^3)$ we let $\varepsilon(u) = (Du + Du')/2 \in L^2(\mathbb{R}^3 ; \mathbb{R}_{\text{sym}}^{3 \times 3})$ denote the standard symmetric gradient. Given any $A, B \in \mathbb{R}_{\text{sym}}^{3 \times 3}$ (3-tensors), we define the triple contraction product $A : B$ as $A : B = A_{ij}B_{ijk}$.

2.2. Reference configuration and boundary displacement

Let the reference configuration of the body be the non-empty, bounded, and connected open set $\Omega \subset \mathbb{R}^3$ with Lipschitz continuous boundary $\Gamma$. Moreover, let $Q = \Omega \times (0, T)$ and $\Sigma = \Gamma \times (0, T)$, for some given final reference time $T > 0$. We will indicate with $u : Q \to \mathbb{R}^3$ the displacement of the body from the reference configuration and prescribe some nonhomogeneous Dirichlet boundary conditions. In particular, we assign the function $u^{\text{Dir}} : Q \to \mathbb{R}^3$ and impose $u \equiv u^{\text{Dir}}$ on $\Sigma$.

In the following, we shall be using Korn’s inequality (see, e.g. Duvaut and Lions,[19] Theorem 3.1, p. 110)

$$\exists c_{\text{Korn}} > 0 : c_{\text{Korn}} \|u\|^2_{H^1(\Omega; \mathbb{R}^3)} \leq \|u\|^2_{L^2(\Gamma; \mathbb{R}^3)} + \|\varepsilon(u)\|^2_{L^2(\Omega; \mathbb{R}_{\text{sym}}^{3 \times 3})} \quad \forall u \in H^1(\Omega; \mathbb{R}^3).$$

(2.1)
2.3. Constitutive relations

Within the small-deformation regime, we additively decompose the deformation

\[ \varepsilon(u) = \varepsilon^{el} + \varepsilon^{tr}, \]

into its elastic part \( \varepsilon^{el} \) and the inelastic (or transformation) part \( \varepsilon^{tr} \).

Moreover, we introduce the additive decomposition of the total stress \( \sigma^{tot} \) into a local part \( \sigma \) and a nonlocal part \( \sigma^{nl} \), namely

\[ \sigma^{tot} = \sigma + \sigma^{nl}. \tag{2.2} \]

We assume elastic material response and hence let the local part \( \sigma \) of the stress fulfill

\[ L\sigma = \varepsilon^{el}, \tag{2.3} \]

where \( L \) is the compliance 4-tensor \( L \equiv C^{-1} \) with

\[ C \equiv 2G \left( I_4 - \frac{1}{3} I_2 \otimes I_2 \right) + K(I_2 \otimes I_2). \tag{2.4} \]

Here \( C \) is the elasticity tensor, \( G > 0 \) is the shear modulus, \( K > 0 \) is the bulk modulus, and \( I_k \) is the identity \( k \)-tensor.

As for the nonlocal stress \( \sigma^{nl} \), we let \((D\varepsilon)_{ij,k} = \varepsilon_{ij,k} \) and assume

\[ (\sigma^{nl})_{ij} = -\mu \varepsilon_{ij,kk}, \tag{2.5} \]

where \( \mu \) is positive. This fourth-order contribution is assumed to give rise to some multi-scale competition, nonlocal effect, or interfacial energy, and within the SMA context can be traced back at least to Falk.\(^{21}\)

We could of course accommodate some more generality by choosing \(-\text{div}(AD\varepsilon)\) for some suitable positive definite 6-tensor \( A \) instead of \(-\mu \varepsilon_{ij,kk} \) (which corresponds to \( \mu I_6 \)). That is, in components, \((\sigma^{nl})_{ij} = -(AD\varepsilon)_{ij,k,k} \). Note that some fourth-order contribution is also considered by Colli et al.\(^{14}\) and by Colli and Sprekels\(^{15}\) where compactness for \( \text{tr} \varepsilon \) is exploited. For instance, the choice in Ref. 14 corresponds to \((\sigma^{nl})_{ij} = -\Delta(\text{div} u)\delta_{ij}, \) (Kronecker) or, taking into account the latter notation \( A_{ijklmn} = \delta_{ij}\delta_{km}\delta_{ln} \). The latter choice is not admissible in our setting as \( A \) is not positive definite.

Among other possible compactifying choices one could consider (see Arndt et al.\(^{1}\))

\[ (\sigma^{nl})_{ij}(x) = \int_{\Omega} K(x, y)(\varepsilon_{ij}(x) - \varepsilon_{ij}(y))dy, \]

for some suitable singular kernel \( K \).
2.4. Inelastic evolution

Let us specify the Drucker–Prager yield function $F$ as

$$F(\sigma) = \varepsilon_L(|s| + 3\alpha p), \quad (2.6)$$

written in terms of the standard decomposition

$$p = (I_2 : \sigma)/3, \quad s = \sigma - pI_2.$$  

Here, $\varepsilon_L > 0$ is a material constant representing a measure of the maximum strain obtainable through alignment of the martensite variants. For $\alpha = 0$, the function $F$ reduces to a function of von Mises type and corresponds to the situation of equal transformation response in traction and compression. The asymmetric behavior of the material model can be modeled by choosing $\alpha \neq 0$ instead.

The yield function $F$ is generally defined up to a constant. On the other hand, $F$ is not a priori non-negative nor bounded below. Indeed, $F$ turns out to be bounded below for all uniaxial tension tests with small $\alpha$. As for hydrostatic tests, any negative value of $F$ is a priori reachable. We shall stress however that the model bears some consistency just within some confined pressure range. Namely, (although math is still consistent) the forthcoming transformation dynamics cannot describe the arbitrarily negative-pressure situation.

Concerning the inelastic part $\varepsilon^{tr}$ of the deformation, we shall specify relation (1.1) in the current nonsmooth setting by letting

$$\varepsilon^{tr} \in \xi \partial F(\sigma). \quad (2.7)$$

We recall that $\xi$ represents the volume fraction of single-variant martensite, and note that $F : \mathbb{R}_{\text{sym}}^{3 \times 3} \to \mathbb{R}$ is convex and positively homogeneous. In particular, the symbol $\partial$ denotes the possibly set-valued subdifferential in the sense of convex analysis.

By combining the elastic response (2.3) and the inelastic ansatz (2.7), we finally obtain the constitutive relation of the material in the form

$$L\sigma + \xi \partial F(\sigma) \ni \varepsilon. \quad (2.8)$$

Before moving on, let us explicitly compute that

$$\partial F(\sigma) = \varepsilon_L(\partial|s| + \alpha I_2).$$

Hence, owing to the above definitions and letting $\theta = (I_2 : \varepsilon)/3$ and $e = \varepsilon - \theta I_2$, one readily checks that relation (2.8) entails

$$s \in 2G(e - \varepsilon_L \xi \partial|s|), \quad p = 3K(\theta - \alpha \varepsilon_L \xi).$$

2.5. Evolution of $\xi$

In the spirit of generalized plasticity models (see Lubliner and Auricchio\textsuperscript{34}), we directly prescribe the evolution of the single-variant martensite volume fraction $\xi$. 

...
In particular, given the input $t \mapsto F(\sigma(t))$, we assume $t \mapsto \xi(t)$ to be given by solving

$$\dot{\xi} + \partial I_{K(F(\sigma))}(\xi) \ni 0, \quad \xi(0) = \xi_0, \quad (2.9)$$

where the non-empty, closed, convex set $K$ is prescribed by means of two non-decreasing and Lipschitz continuous functions $\lambda_\ell, \lambda_u : \mathbb{R} \to [0, 1]$ as

$$K(F) = [\lambda_\ell(F), \lambda_u(F)] \quad \forall F \geq 0.$$

Relation (2.9) is generally referred to as a generalized play operator (we refer to Brokate and Sprekels, Krasnosel’skii and Pokrovskii, and Visintin or a sweeping process driven by $K$ (see Monteiro Marques and Moreau). In particular, the evolution in (2.9) is rate-independent and the input–output behavior for (2.9) is depicted in Fig. 1. Note that horizontal paths ($\xi$ constant) are reversible whereas $\xi$ can just increase (decrease) along $\xi = \lambda_\ell(F(\sigma))$ ($\xi = \lambda_u(F(\sigma))$, respectively).

Owing to the specific form (2.6) of $F$ we readily check that one can rewrite the evolution problem (2.9) in terms of $\varepsilon = \varepsilon(u)$ only (see Auricchio and Stefanelli). To this aim, we shall invert the constitutive relation (2.8). Indeed, we first observe that the compliance 4-tensor $L$ can be expressed as

$$L = \frac{1}{2G} \text{dev} + \frac{1}{9K} I_2 \text{tr},$$

where dev is the projection of $\mathbb{R}^{3\times3}_{\text{sym}}$ onto $\mathbb{R}^{3\times3}_{\text{dev}} : = \{ \eta \in \mathbb{R}^{3\times3}_{\text{sym}} \text{ such that } \eta : I_2 = 0 \}$ and tr is the trace operator given by $\text{tr} \eta \doteq \eta : I_2$. Moreover, every element $\varphi \in \partial F(\sigma)$ admits the representation

$$\varphi = \varepsilon_L(\eta + \alpha I_2),$$

with

$$\eta \begin{cases} \in B_1(0) \cap \mathbb{R}^{3\times3}_{\text{dev}} & \text{if dev } \sigma = 0, \\ = \frac{\text{dev } \sigma}{|\text{dev } \sigma|} & \text{if dev } \sigma \neq 0. \end{cases}$$

Fig. 1. Diagram of the evolution of $\xi$. 
Then, the constitutive relation (2.8) is equivalent to
\[ \text{dev} \varepsilon = \frac{1}{2G} \text{dev} \sigma + \varepsilon_L \xi \eta, \]
\[ \text{tr} \varepsilon = \frac{1}{3K} \text{tr} \sigma + 3 \varepsilon_L \alpha \xi I_2. \]
As we have that \( \eta : \text{dev} \sigma = |\eta||\text{dev} \sigma| \), we conclude for
\[ |\text{dev} \varepsilon| = \frac{1}{2G} |\text{dev} \sigma| + \varepsilon_L \xi |\eta|, \]
and the inverse relation reads
\[ |\text{dev} \sigma| = 2G(|\text{dev} \varepsilon| - \varepsilon_L \xi)^+, \]
where \((\cdot)^+ = \max\{\cdot, 0\}\) is the usual positive part. The constitutive mapping \( H : (\xi, \varepsilon) \mapsto \sigma \) can thus be written explicitly as
\[ \sigma = 2G(|\text{dev} \varepsilon| - \varepsilon_L \xi)^+ \frac{\text{dev} \varepsilon}{|\text{dev} \varepsilon|} + K(\text{tr} \varepsilon - 3 \varepsilon_L \alpha \xi)I_2. \quad (2.10) \]
In particular, the mapping \( \hat{F} = F \circ H \) has the form
\[ \hat{F}(\xi, \varepsilon) = \varepsilon_L(2G(|\text{dev} \varepsilon| - \varepsilon_L \xi)^+ + 3K \alpha \text{tr} \varepsilon - 9 \varepsilon_L K \alpha^2 \xi). \]
Now, let us define the functions \( \hat{\lambda}_\ell(\varepsilon), \hat{\lambda}_u(\varepsilon) \) by letting
\[ \lambda_i(\hat{F}(\xi, \varepsilon)) = \xi \Leftrightarrow \xi = \hat{\lambda}_i(\varepsilon) \quad \text{for } i = \ell, u. \]
Since \( \hat{F} \) is decreasing in \( \xi \), the mappings \( \hat{\lambda}_\ell(\varepsilon), \hat{\lambda}_u(\varepsilon) \) turn out to be well defined. Introducing \( \hat{K} : \mathbb{R}^{3 \times 3}_{\text{sym}} \to \mathbb{R}^{[0,1]} \) by setting
\[ \hat{K}(\varepsilon) = [\hat{\lambda}_\ell(\varepsilon), \hat{\lambda}_u(\varepsilon)] \quad \forall \varepsilon \in \mathbb{R}^{3 \times 3}_{\text{sym}}, \]
relation (2.9) finally turns out to be equivalent to
\[ \dot{\xi} + \partial I_{\hat{K}(\varepsilon)}(\xi) \ni 0, \quad \xi(0) = \xi_0. \quad (2.11) \]
We shall use this possible equivalent formulation for the evolution of \( \xi \) in the following. Let us just stress that \( \hat{\lambda}_\ell, \hat{\lambda}_u \) are Lipschitz continuous and that both \( K \) and \( \hat{K} \) are Lipschitz continuous in the standard Hausdorff metric with respect to input variation. Recall that the Hausdorff distance between two non-empty sets \( A, B \subset E \), \( E \) being a normed set with norm \( |\cdot|_E \), is given by
\[ d_E(A, B) = \max\left\{ \sup_{a \in A} \inf_{b \in B} |a - b|_E, \sup_{b \in B} \inf_{a \in A} |a - b|_E \right\}. \]
2.6. Associativity

The ATL model turns out to be associative in the standard plasticity sense (see Han and Reddy\textsuperscript{26}). The associative structure of the ATL model is revealed by defining the Gibbs energy density \( G \) and the dissipation density \( D \) as

\[
G(\sigma, \xi) \doteq -\frac{1}{2} \sigma : L \sigma - \xi F(\sigma) + h(\xi),
\]

\[
D(\sigma, \xi, \dot{\xi}) \doteq \sup \{ \dot{\xi} q : q \in -K(F(\sigma)) - F(\sigma) + h'(\xi) + \xi \},
\]

with \( h \) given by

\[
h(\xi) := \int_{\xi_0}^{\xi} \lambda_m^{-1}(\xi) d\xi, \quad \xi_0 \in (\inf \lambda, \sup \lambda),
\]

where \( \lambda_m := (\lambda + \lambda_u)/2 \) is the midline between \( \lambda \) and \( \lambda_u \), and \( \lambda_m^{-1} \) is a fixed selection of the inverse (in the sense of maximal monotone graphs) of \( \lambda_m \). Indeed, \( D \) turns out to be the partial Legendre conjugate \( I_{-K(F(\sigma)) - F(\sigma) + h'(\xi) + \xi} \) (with respect to \( \dot{\xi} \)) of the indicator function of the moving convex set \( -K(F(\sigma)) - F(\sigma) + h'(\xi) + \xi \) and we readily compute that

\[
\partial_\sigma (-G(\sigma, \xi)) = L \sigma + \xi \partial F(\sigma) = \varepsilon,
\]

\[
-\partial_\xi G(\sigma, \xi) = F(\sigma) - h'(\xi),
\]

\[
\partial_\xi D(\sigma, \xi, \dot{\xi}) = \partial_\xi I_{-K(F(\sigma)) - F(\sigma) + h'(\xi) + \xi} \dot{\xi},
\]

with obvious notation for partial subdifferentials. Hence, the constitutive relation (2.8) and the flow rule (2.9) can be rewritten as the system

\[
\partial_{(\sigma, \xi)} D(\sigma, \xi, \dot{\xi}) + \partial_{(\sigma, \xi)} (-G(\sigma, \xi)) \geq \begin{pmatrix} \varepsilon \\ 0 \end{pmatrix}, \quad \xi(0) = \xi_0.
\]

An associative formulation for the ATL model in the variables \( (\varepsilon, \xi) \) is available upon choosing the free energy density \( \psi \) and the dissipation density \( \tilde{D} \) as

\[
\psi(\varepsilon, \xi) \doteq \sup_{\sigma \in \mathbb{R}^{3 \times 3}} \{ \varepsilon : \sigma + G(\sigma, \xi) \},
\]

\[
\tilde{D}(\varepsilon, \xi, \dot{\xi}) \doteq \sup \{ \dot{\xi} q : q \in -\tilde{K}(\varepsilon) + \tilde{F}(\xi, \varepsilon) - h'(\xi) + \xi \}.
\]

In particular, by recalling that \(-G\) is the partial Legendre conjugate of \( \psi \) with respect to \( \varepsilon \), we get

\[
\partial_\varepsilon \psi(\varepsilon, \xi) = \sigma,
\]

\[
\partial_\xi \psi(\varepsilon, \xi) = \partial_\xi G(\sigma, \xi) = -F(\sigma) + h'(\xi) = -\tilde{F}(\xi, \varepsilon) + h'(\xi),
\]

\[
\partial_\xi \tilde{D}(\varepsilon, \xi, \dot{\xi}) = \partial_\xi I_{-\tilde{K}(\varepsilon) + \tilde{F}(\xi, \varepsilon) - h'(\xi) + \xi} \dot{\xi}.
\]

Hence, the constitutive relation (2.8) and the flow rule (2.11) turn out to be

\[
\partial_{(\varepsilon, \xi)} \tilde{D}(\varepsilon, \xi, \dot{\xi}) + \partial_{(\varepsilon, \xi)} \psi(\varepsilon, \xi) \geq \begin{pmatrix} \sigma \\ 0 \end{pmatrix}, \quad \xi(0) = \xi_0.
\]
Let us explicitly mention that, despite the associative variational structure of the ATL model, classical existence results for quasi-variational inequalities seem not directly applicable to the ATL model, the basic obstruction in this direction being the non-smoothness of the related functionals. On the other hand, at least for the zero-dimensional constitutive problem, some ad hoc analysis based on order methods in the spirit of Rossi and Stefanelli may be considered. We shall develop these considerations elsewhere.

Given the above introduced associative reformulations \((2.12)\)–\((2.13)\), the thermodynamic consistency of the ATL model can be readily checked. Indeed, for all suitably smooth evolutions, the Clausius–Duhem inequality holds in either one of the following equivalent forms

\[
\dot{\varepsilon} : \sigma - \frac{d}{dt}(\varepsilon : \sigma + G) = -\dot{G} - \varepsilon : \dot{\sigma} = \dot{\xi}(F(\varepsilon) - h'(\xi)) \geq 0, \tag{2.9}
\]

\[
\frac{d}{dt}(\psi - \varepsilon : \sigma) + \varepsilon : \dot{\sigma} = \dot{\psi} - \sigma : \dot{\varepsilon} = -\dot{\xi}(\hat{F}(\xi, \varepsilon) - h'(\xi)) \leq 0. \tag{2.11}
\]

2.7. Quasistatic equilibrium

By coupling to the above-introduced constitutive relation \((2.8)\) and the evolution law for \(\xi\) in \((2.9)\) with the quasistatic equilibrium system, we are led to consider the problem of finding the displacement \(u : Q \rightarrow \mathbb{R}^3\), the (local) stress \(\sigma : Q \rightarrow \mathbb{R}^{3 \times 3}_{\text{sym}}\), and the single-variant martensitic volume fraction \(\xi : Q \rightarrow [0, 1]\) of the body such that

\[
\begin{align*}
\text{div } \sigma^{\text{tot}} + b &= 0 \quad \text{on } Q, \tag{2.14} \\
u &= u^\text{Dir} \quad \text{on } \Gamma, \tag{2.15} \\
\mu \varepsilon_{ij,k}(u)n_k &= 0 \quad \text{on } \Sigma, \tag{2.16} \\
\dot{\sigma} + \xi \partial F(\sigma) &\ni \varepsilon \quad \text{on } Q, \tag{2.17} \\
\dot{\xi} + \partial I_K(F(\sigma))(\xi) &\ni 0 \quad \text{on } Q, \tag{2.18} \\
\xi(0) &= \xi_0 \quad \text{on } \Omega. \tag{2.19}
\end{align*}
\]

Here, \(b\) is the body force density, \(u^\text{Dir}\) is the given boundary displacement, \(n\) is the outward normal to \(\Gamma\), and \(\xi_0 : \Omega \rightarrow [0, 1]\) is a given initial volume fraction of single-variant martensite.

3. Main Existence Result

The main issue of the paper is that of providing an existence result for the quasistatic evolution problem. In particular, we will focus on a variational formulation of the system in \((2.14)\)–\((2.19)\). In order to introduce the notion of weak solution we
shall be dealing with, we multiply Eq. (2.14) by \( v \in C^\infty_c(\Omega; \mathbb{R}^3) \) and integrate on \( \Omega \) in order to get
\[
\int_\Omega (\sigma + \sigma^{nl}) : \varepsilon(v) = \int_\Omega b \cdot v. \tag{3.1}
\]

By taking into account the boundary condition (2.16), we have
\[
\int_\Omega \sigma^{nl} : \varepsilon(v) = - \int_\Omega \mu D \varepsilon(u) : D \varepsilon(v) + \int_\Omega \mu \varepsilon_{ij,kk}(u) \varepsilon_{ij}(v) = - \int_{\Gamma} \mu \varepsilon_{ij,k} u \varepsilon_{ij,k}(v) n_k d\Gamma + \int_\Omega \mu \varepsilon_{ij,k}(u) \varepsilon_{ij,k}(v),
\]
and (3.1) yields
\[
\int_\Omega (\mu D \varepsilon(u) : D \varepsilon(v) + \sigma : \varepsilon(v)) = \int_\Omega b \cdot v.
\]

Let us write
\[
u = w + u^{\text{Dir}},
\]
where we recall that the function \( u^{\text{Dir}} \) is defined on the whole \( \overline{\Omega} \), and introduce the spaces and the functional
\[
W \doteq \mathcal{X}^1(\Omega; \mathbb{R}^3), \quad V = \{ w \in W : \varepsilon(w) \in \mathcal{X}^1(\Omega; \mathbb{R}^{3 \times 3}_{\text{sym}}), w = 0 \text{ on } \Gamma \},
\]
\[
\langle f, v \rangle := \int_\Omega b \cdot v - \int_\Omega \mu D \varepsilon(u^{\text{Dir}}) : D \varepsilon(v) \quad \forall v \in V.
\]

We make the following assumptions on data
\[
b \in \mathcal{X}^1(0,T; L^2(\Omega; \mathbb{R}^3)),
\]
\[
u^{\text{Dir}} \in \mathcal{X}^1(0,T; W), \quad \varepsilon(u^{\text{Dir}}) \in \mathcal{X}^1(0,T; \mathcal{X}^1(\Omega; \mathbb{R}^{3 \times 3}_{\text{sym}})).
\]
Furthermore, we suppose that the initial data satisfy
\[
w^0 \in V, \quad \sigma^0 \in L^2(\Omega; \mathbb{R}^{3 \times 3}_{\text{sym}}), \quad \xi^0 \in L^2(\Omega),
\]
\[
\int_\Omega (\mu D \varepsilon(w^0) : D \varepsilon(v) + \sigma^0 : \varepsilon(v)) = \langle f_0, v \rangle \quad \forall v \in V,
\]
\[
\xi^0 \in K(F(\sigma^0)), \quad L \sigma^0 + \xi^0 \partial F(\sigma^0) \supset \varepsilon(w^0 + u^0) \quad \text{a.e. in } \Omega,
\]
where \( f_0 = f(0) \) and \( u_0^{\text{Dir}} = u^{\text{Dir}}(0) \). We shall be concerned with the following problem.

**Definition 3.1.** (Quasistatic evolution problem) To find
\[
w \in \mathcal{X}^1(0,T; V), \quad \sigma \in \mathcal{X}^1(0,T; L^2(\Omega; \mathbb{R}^{3 \times 3}_{\text{sym}})), \quad \text{and} \quad \xi \in \mathcal{X}^1(0,T; L^2(\Omega))
\]
such that
\[
\int_{\Omega} (\mu D\varepsilon(w) \cdot D\varepsilon(v) + \sigma : \varepsilon(v)) = (f, v) \quad \forall v \in V, \quad \text{a.e. in } (0, T),
\] (3.7)

\[
L\sigma + \xi \partial F(\sigma) \ni \varepsilon(w + u_{\text{Dir}}) \quad \text{a.e. in } Q,
\] (3.8)

\[
\dot{\xi} + \partial I_{K(\varepsilon(\sigma))}(\xi) \ni 0 \quad \text{a.e. in } Q,
\] (3.9)

\[
w(0) = w^0 \quad \text{in } V,
\] (3.10)

Our main result reads as follows.

**Theorem 3.1.** (Existence for the quasistatic evolution problem) Let (3.2)–(3.6) hold. Then, the quasistatic evolution problem admits a solution.

The proof of Theorem 3.1 will be carried out in the remainder of the paper by means of a time-discretization argument. In particular, we will pass to the limit as the fineness of the time-partition goes to zero in a sequence of approximating trajectories which are obtained by solving an incremental step-problem. As the whole evolution is indeed rate-independent, the incremental problem turns out to bear a specific interest in itself and is here explicitly stated for the sake of definiteness.

**Definition 3.2.** (Incremental problem) Given \( \hat{f} \in V^* \), \( \hat{\xi} \in L^2(\Omega) \) and \( u_{\text{Dir}} \in W \), to find \( w \in V \), \( \sigma \in L^2(\Omega; \mathbb{R}^{3 \times 3}) \), and \( \xi \in L^2(\Omega) \) such that
\[
\int_{\Omega} (\mu D\varepsilon(w) \cdot D\varepsilon(v) + \sigma : \varepsilon(v)) = (\hat{f}, v) \quad \forall v \in V,
\] (3.11)

\[
L\sigma + \xi \partial F(\sigma) \ni \varepsilon(w + u_{\text{Dir}}) \quad \text{a.e. in } \Omega,
\] (3.12)

\[
(\xi - \hat{\xi}) + \partial I_{K(\varepsilon(\sigma))(\xi)}(\xi) \ni 0 \quad \text{a.e. in } \Omega.
\] (3.13)

4. Existence for the Incremental Problem

In preparation of the proof of Theorem 3.1 we shall check for the following.

**Theorem 4.1.** (Existence for the incremental problem) The Incremental Problem has a solution.

The rest of this section is devoted to the proof of this result. We aim at applying Schauder’s fixed-point theorem. Given \( \tilde{w} \in W \), from relation (3.13) we firstly determine

\[
\tilde{\xi} = (1 + \partial I_{K(\varepsilon(\tilde{w} + u_{\text{Dir}}}))^{-1}(\tilde{\xi}),
\]

namely, \( \tilde{\xi} \) is almost everywhere the pointwise projection of \( \tilde{\xi} \) onto the interval \( K(\varepsilon(\tilde{w} + u_{\text{Dir}})) \). Secondly we consider the following sub-problem.
**Definition 4.1.** (Equilibrium incremental problem) Given \( \tilde{f} \in V^* \), \( \tilde{\xi} \in L^2(\Omega) \) and \( u^{\text{Dir}} \in W \), to find \( w \in V \) and \( \sigma \in L^2(\Omega; \mathbb{R}^{3 \times 3}_{\text{sym}}) \) such that

\[
\int_{\Omega} (\mu D\varepsilon(w) : D\varepsilon(v) + \sigma : \varepsilon(v)) = \langle \tilde{f}, v \rangle \quad \forall \ v \in V,
\]

\[
L\sigma + \tilde{\xi}\partial F(\sigma) \ni \varepsilon(w + u^{\text{Dir}}) \quad \text{a.e. in } \Omega.
\]

The Equilibrium Incremental Problem will be shown to possess a unique solution. The map \( \tilde{w} \mapsto w \), where \( w \) is the solution of the Equilibrium Incremental Problem, will turn out to have a fixed point, which in turn solves the Incremental Problem.

We start from the following.

**Lemma 4.1.** (Well-posedness of the equilibrium incremental problem) The Equilibrium Incremental Problem has a unique solution.

**Proof.** We first prove the existence. Let us introduce the function \( W^* : [0,1] \times \mathbb{R}^{3 \times 3}_{\text{sym}} \to \mathbb{R} \) as

\[
W^*(\xi,\sigma) = \frac{1}{2} \sigma : L\sigma + \xi F(\sigma) - \varepsilon(u^{\text{Dir}}) : \sigma
\]

and its partial Legendre conjugate with respect to \( \sigma \)

\[
W(\xi,\varepsilon) = \sup_{\sigma \in \mathbb{R}^{3 \times 3}_{\text{sym}}} (\varepsilon : \sigma - W^*(\xi,\sigma)).
\]

This allows us to rewrite (4.2) as

\[
\varepsilon(w) \in \partial\varepsilon W^*(\tilde{\xi},\sigma) \quad \text{or} \quad \sigma \in \partial\varepsilon W(\tilde{\xi},\varepsilon(w)) \quad \text{a.e. in } \Omega.
\]

The Equilibrium Incremental Problem (4.1)–(4.2) is equivalent to the following minimization problem

\[
\min_{w \in V} I(w)
\]

for the functional \( I : W \to \mathbb{R} \) defined by

\[
I(w) = \int_{\Omega} \left( \frac{\mu}{2} |D\varepsilon(w)|^2 + W(\tilde{\xi},\varepsilon(w)) \right) - \langle \tilde{f}, w \rangle.
\]

Henceforth \( c, c' \) will stand for any positive constant, possibly depending on data and varying from line to line.

It is now easy to see that problem (4.3) has a solution since \( I \) is continuous and coercive in \( V \). Indeed, we readily check that

\[
W^*(\tilde{\xi},\sigma) \leq c(1 + |\sigma|^2) \quad \forall \sigma \in \mathbb{R}^{3 \times 3}_{\text{sym}}.
\]
Hence, we can write
\[
W(\tilde{\varepsilon}, \varepsilon) \geq \sup_{\sigma \in \mathbb{R}^{2,3}} \frac{1}{2} \int (|\varepsilon| + |\sigma|^2) = \sup_{\varepsilon > 0} \sup_{\sigma > 0} (\varepsilon|\varepsilon| - c) = \frac{1}{4c} - c.
\]
By means of Korn’s inequality (2.1) we therefore have
\[
I(w) \geq c\|\varepsilon(w)\|_{W^1}^2 - \|\tilde{f}\|_{L^2} \|w\|_{V} - c
\]
\[
\geq \frac{c}{2} \|\varepsilon(w)\|_{W^1}^2 + \frac{c}{2}c_{Korn}\|w\|_{W^1}^2 - \|\tilde{f}\|_{L^2} \|w\|_{V} - c
\]
\[
\geq c \|w\|_{W^1}^2 - \|\tilde{f}\|_{L^2} \|w\|_{V} - c,
\]
and coercivity follows.

In order to prove the uniqueness for the Equilibrium Incremental Problem, let \(w_1, w_2 \in V\) be two solutions and check that
\[
\sigma_1 = \sigma_2, \quad D\varepsilon(w_1 - w_2) = 0 \quad \text{a.e. in } \Omega.
\]
Indeed, by writing problem (4.1)–(4.2) for two solutions \(w_1, \sigma_1\) and \(w_2, \sigma_2\), taking the difference of the two equations (4.1) and testing by \(w_1 - w_2\), we get
\[
\int_{\Omega} (\mu|D\varepsilon(w_1 - w_2)|^2 + (\sigma_1 - \sigma_2) : \varepsilon(w_1 - w_2)) = 0.
\]
On the other hand, by the monotonicity of \(\partial F\) we can write
\[
((\varepsilon(w_1) - L\sigma_1) - (\varepsilon(w_2) - L\sigma_2)) : (\sigma_1 - \sigma_2)
\]
\[
= (\varepsilon(w_1 - w_2) - L(\sigma_1 - \sigma_2)) : (\sigma_1 - \sigma_2) \geq 0,
\]
and hence
\[
(\sigma_1 - \sigma_2) : \varepsilon(w_1 - w_2) \geq L(\sigma_1 - \sigma_2) : (\sigma_1 - \sigma_2) \geq c|\sigma_1 - \sigma_2|^2 \geq 0.
\]
Hence we have the equalities (4.4) and the boundary condition \(w = 0\) on \(\Gamma\) entails \(w_1 = w_2\). Indeed, by setting \(\tilde{w} = w_1 - w_2\) and integrating \(\varepsilon_{ik}(\tilde{w})\) we get
\[
\int_{\Omega} \varepsilon_{ik}(\tilde{w}) = \frac{1}{2} \int_{\Omega} (\frac{\partial \tilde{w}_i}{\partial x_k} + \frac{\partial \tilde{w}_k}{\partial x_i}) = \frac{1}{2} \int_{\Gamma} (\tilde{w}_i n_k + \tilde{w}_k n_i) = 0.
\]
Hence, by Poincaré’s inequality and the fact that \(D\varepsilon(\tilde{w}) = 0\) we have that \(\varepsilon(\tilde{w}) = 0\). From Korn’s inequality (2.1) we finally deduce \(\tilde{w} = 0\).

We now turn to the proof of Theorem 4.1. Let us introduce the set \(M \subset W\) defined by
\[
M = \left\{ w \in V : \int_{\Omega} (|D\varepsilon(w)|^2 + |\varepsilon(w)|^2) \leq c_0, w = 0 \text{ on } \Gamma \right\},
\]
where \(c_0\) is a positive constant to be defined later and introduce the operator \(S : M \rightarrow V \subset W\), defined as the composition \(S = S_2 \circ S_1\), where \(S_1 : M \rightarrow L^2(\Omega)\).
is given by
\[ S_1(\tilde{w}) \doteq (1 + \partial I_{\tilde{K}(\varepsilon(\tilde{w} + u_{\text{Dir}})))}^{-1}(\tilde{\xi}), \]
for every \( \tilde{w} \in M \). Note that the nonlinear operator \( S_1 \) is nothing but the pointwise projection of \( \tilde{\xi} \) on the closed interval \( \tilde{K}(\varepsilon(\tilde{w} + u_{\text{Dir}})) \). It is easy to check that, due to the Lipschitz continuity of the map \( \tilde{F} \rightarrow \tilde{K}(\tilde{F}) \), the operator \( S_1 \) fulfills
\[
\| S_1(\tilde{w}_1) - S_1(\tilde{w}_2) \|_{L^2(\Omega)} \leq c\| \varepsilon(\tilde{w}_1 - \tilde{w}_2) \|_{L^2(\Omega;\mathbb{R}^{3\times3})}; \tag{4.6}
\]
and it is hence globally Lipschitz continuous from \( W \) to \( L^2(\Omega) \). Moreover, \( S_2 : L^2(\Omega) \rightarrow V \subset W \) is defined to be such that \( S_2(\tilde{\xi}) \) is the unique solution \( w \in V \subset W \) to the Equilibrium Incremental Problem with data \( \tilde{f} = f \in V^* \), \( \xi = \tilde{\xi} \in L^2(\Omega) \), and \( u_{\text{Dir}} \in W \).

The set \( M \) is clearly convex and closed in \( W \). It is moreover easy to verify that it is also compact in \( W \). For the sake of applying Schauder’s theorem (see Baiocchi and Capelo\textsuperscript{12}), we need to check that, for \( c_0 \) sufficiently large, one has that \( S(M) \subset M \), \( \overline{S(M)} \) (closure in \( W \)) is compact in \( W \), and \( S : W \rightarrow W \) is continuous.

Take \( \tilde{w} \in M \). Then \( w \doteq S(\tilde{w}) \) and \( \tilde{\xi} \doteq S_1(\tilde{w}) \) satisfy
\[
\int_{\Omega} (|\mu|D\varepsilon(w)|^2 + \sigma : \varepsilon(w)) = (\tilde{f}, w), \tag{4.7}
\]
\[
\sigma + \tilde{\xi}C\partial F(\sigma) \geq C\varepsilon(w + u_{\text{Dir}}) \quad \text{a.e. in } \Omega, \tag{4.8}
\]
along with a stress \( \sigma \in L^2(\Omega;\mathbb{R}^{3\times3}) \). Hence, we have that
\[
\sigma = C\varepsilon(w + u_{\text{Dir}}) - \tilde{\xi}C\eta,
\]
for a selection \( \eta \) such that \( \eta \in \partial F(\sigma) \) almost everywhere in \( \Omega \) and
\[
\sigma : \varepsilon(w) = C\varepsilon(w + u_{\text{Dir}}) : \varepsilon(w) - \tilde{\xi}C\eta : \varepsilon(w) \geq c|\varepsilon(w)|^2 - \frac{1}{c},
\]
where we have used the fact that \( \partial F \) is bounded and \( \tilde{\xi} \in [0, 1] \). Hence, from (4.7) and (4.8) we get
\[
\int_{\Omega} (|D\varepsilon(w)|^2 + |\varepsilon(w)|^2) \leq \epsilon'. \tag{4.9}
\]
If we now choose \( c_0 = \epsilon' \), we obtain that \( S(M) \subset M \).

The compactness of \( S(M) \) in \( W \) is now an immediate consequence of the inclusion \( S(M) \subset M \) and of the compactness of \( M \) in \( W \).

It remains to prove the continuity of \( S \) in the strong topology of \( W \). To this aim, let \( \tilde{w}_n \rightarrow \tilde{w} \) in \( W \) and set \( \xi_n = S_1(\tilde{w}_n) \). Due to (4.6), we have \( \xi_n \rightarrow \xi \), strongly in \( L^2(\Omega) \), where \( \tilde{\xi} = S_1(\tilde{w}) \). On the other hand, setting \( w_n = S(\tilde{w}_n) \), from
estimate (4.9) we have \( ||\varepsilon(w_n)||_{H^1(\Omega; R^{3x3}_{sym})} \leq c \), which implies that there exists a not relabeled subsequence and an element \( w \in V \) such that

\[
\varepsilon(w_n) \rightharpoonup \varepsilon(w) \quad \text{strongly in} \quad L^2(\Omega; R^{3x3}_{sym}) \quad \text{and weakly in} \quad H^1(\Omega; R^{3x3}_{sym}).
\]

We now have to check that indeed the latter convergence holds for the whole sequence and that \( w = S(\tilde{w}) \). Since \( w_n \), together with \( \sigma_n \), solves the Equilibrium Incremental Problem with data \( \tilde{f} \) and \( \tilde{\xi}_n \), we obtain

\[
\int_{\Omega} \mu |D \varepsilon(w_n - w_m)|^2 + \int_{\Omega} (\sigma_n - \sigma_m) : \varepsilon(w_n - w_m) = 0,
\]

(4.11)

\[
L(\sigma_n - \sigma_m) + \tilde{\xi}_n (\eta_n - \eta_m) = \varepsilon(w_n - w_m) - \eta_m (\tilde{\xi}_n - \tilde{\xi}_m) \quad \text{a.e. in} \ \Omega,
\]

(4.12)

for some \( \eta \in \partial F(\sigma) \) almost everywhere in \( \Omega \), for \( i = n, m \). Now, from (4.12), by using the monotonicity and the boundedness of \( \partial F \), we get

\[
c|\sigma_n - \sigma_m|^2 \leq \varepsilon(w_n - w_m) : (\sigma_n - \sigma_m) + \frac{1}{c} |\tilde{\xi}_n - \tilde{\xi}_m|^2,
\]

and hence, (4.11) yields

\[
\int_{\Omega} \mu |D \varepsilon(w_n - w_m)|^2 + c \int_{\Omega} |\sigma_n - \sigma_m|^2 \leq \frac{1}{c} \int_{\Omega} |\tilde{\xi}_n - \tilde{\xi}_m|^2.
\]

(4.13)

From this last estimate we obtain that \( D \varepsilon(w_n) \) and \( \sigma_n \) are Cauchy sequences in \( L^2 \). By (4.10), we have that \( D \varepsilon(w_n) \rightharpoonup D \varepsilon(w) \) strongly in \( L^2(\Omega; R^{3x3}_{sym}) \). Moreover, there exists \( \sigma \in L^2(\Omega; R^{3x3}_{sym}) \) such that \( \sigma_n \rightarrow \sigma \) strongly in \( L^2(\Omega; R^{3x3}_{sym}) \). It is now immediate to pass to the limit in (4.1), written for \( w_n, \sigma_n \) and with datum \( \tilde{f} \).

Next, by extracting a further (non-relabeled) subsequence, we can also assume the pointwise convergences \( \tilde{\xi}_n \rightarrow \tilde{\xi} \), \( \sigma_n \rightarrow \sigma \) and \( \varepsilon(w_n) \rightarrow \varepsilon(w) \) a.e. in \( \Omega \) and this allows to pass to the limit also in (4.2), written for \( w_n, \sigma_n \) and \( \tilde{\xi}_n \). Hence, we conclude that \( w \) and \( \sigma \) solve

\[
\int_{\Omega} \langle \mu D \varepsilon(w) \cdot D \varepsilon(v) + \sigma : \varepsilon(v) \rangle = \langle \tilde{f}, v \rangle \quad \forall v \in V,
\]

\[
L \sigma + \tilde{\xi} \partial F(\sigma) \ni \varepsilon(w + u^{Div}) \quad \text{a.e. in} \ \Omega,
\]

namely \( w = S(\tilde{w}) \). Finally, the convergence for the whole sequence follows from the uniqueness of the solution of the Equilibrium Incremental Problem (4.1)–(4.2) (see Lemma 4.1).

5. Proof of Theorem 3.1

We shall make use of a time-discretization scheme. Let us introduce the uniform partition \( \{0 = t_0 < t_1 < \cdots < t_{N-1} < t_N = T\} \) with \( t_i = i\tau \), for \( i = 0, \ldots, N \), where \( \tau \) is the diameter and \( N \tau = T \). Letting \( \{z_i\}_{i=0}^{N} \) be a vector, we denote by \( z_\tau \) and \( z_\tau \) two functions of the time interval \([0, T]\) which interpolate the values
of the vector \( \{z_i\} \) piecewise linearly and backward constantly on the partition, respectively. Namely,

\[
z_t(0) = z_0, \quad z_t(t) = \gamma_i(t)z_i + (1 - \gamma_i(t))z_{i-1},
\]

\[
\tau_z(0) = z_0, \quad \tau_z(t) = z_i, \quad \text{for} \quad t \in ((i-1)\tau, i\tau], \quad i = 1, \ldots, N,
\]

where

\[
\gamma_i(t) = (t - (i - 1)\tau)/\tau \quad \text{for} \quad t \in ((i-1)\tau, i\tau], \quad i = 1, \ldots, N.
\]

Setting \( f_i = f(t_i) \) and \( u^{\text{Dir}} = u^{\text{Dir}}(t_i) \), we now inductively construct a discrete solution to the Incremental Problem. Namely, we obtain \( \{w_i\}_{i=0}^N \in V^{N+1}, \{\sigma_i\}_{i=0}^N \in (L^2(\Omega; \mathbb{R}^{3 \times 3}))^{N+1}, \) and \( \{\xi_i\}_{i=0}^N \in (L^2(\Omega))^{N+1} \) such that

\[
w_0 = w^0 \quad \text{in} \quad V, \quad \sigma_0 = \sigma^0, \quad \xi_0 = \xi^0 \quad \text{a.e. in} \quad \Omega, \quad (5.1)
\]

\[
\int_{\Omega} (\mu D\varepsilon(w_i) : D\varepsilon(v) + \sigma_i : \varepsilon(v)) = (f_i, v) \quad \forall v \in V, \quad \text{for} \quad i = 1, \ldots, N, \quad (5.2)
\]

\[
L\sigma_i + \xi_i \partial F(\sigma_i) \ni \varepsilon(w_i + u^{\text{Dir}}) \quad \text{a.e. in} \quad \Omega, \quad \text{for} \quad i = 1, \ldots, N, \quad (5.3)
\]

\[
\xi_i - \xi_{i-1} + \partial I_{K(F(\sigma_i))}(\xi_i) \ni 0 \quad \text{a.e. in} \quad \Omega, \quad \text{for} \quad i = 1, \ldots, N. \quad (5.4)
\]

### 5.1. A priori estimates

Since \( w_i \) satisfies (4.9) for \( i = 1, \ldots, N \) (the constant on the right of (4.9) being independent of \( \xi_i \)), we have that

\[
\|w_t\|_{L^\infty(0,T;V)} \leq c,
\]

where here and henceforth all constants \( c \) are independent of \( \tau \). Taking the difference in (5.2)–(5.3) for two consecutive time-steps we obtain that

\[
\int_{\Omega} \mu |D\varepsilon(w_i - w_{i-1})|^2 + \int_{\Omega} (\sigma_i - \sigma_{i-1}) : \varepsilon(w_i - w_{i-1})
\]

\[
= (f_i - f_{i-1}, w_i - w_{i-1}), \quad (5.5)
\]

\[
L(\sigma_i - \sigma_{i-1}) + \xi_{i-1}(\eta_i - \eta_{i-1}) + (\xi_i - \xi_{i-1})\eta_i - \varepsilon(u_{\text{Dir}}^i - u_{\text{Dir}}^{i-1})
\]

\[
= \varepsilon(w_i - w_{i-1}) \quad \text{a.e. in} \quad \Omega, \quad (5.6)
\]

for \( \eta_j \in \partial F(\sigma_j) \) almost everywhere, \( j = i, i-1 \), and \( i = 1, \ldots, N \). If now we multiply Eq. (5.6) by \( (\sigma_i - \sigma_{i-1}) \), we have to consider the term \( (\xi_i - \xi_{i-1})\eta_i(\sigma_i - \sigma_{i-1}) \). We aim to show that the latter is almost everywhere non-negative. Indeed, wherever \( \xi_i > \xi_{i-1} \), then \( F(\sigma_i) > F(\sigma_{i-1}) \) and

\[
(\xi_i - \xi_{i-1})\eta_i(\sigma_i - \sigma_{i-1}) \geq (\xi_i - \xi_{i-1})(F(\sigma_i) - F(\sigma_{i-1})) \geq 0. \quad (5.7)
\]
An analogous trick applies to the points in $\Omega$ where $\xi_i < \xi_{i-1}$. Hence, we have
\[
L(\sigma_i - \sigma_{i-1}) : (\sigma_i - \sigma_{i-1}) \\
\leq \varepsilon(w_i - w_{i-1}) : (\sigma_i - \sigma_{i-1}) + \varepsilon(u_i^{\text{Dir}} - u_{i-1}^{\text{Dir}}) : (\sigma_i - \sigma_{i-1})
\]
and, recalling (5.5),
\[
\int_{\Omega} (\mu \varepsilon(w_i - w_{i-1}))^2 + L(\sigma_i - \sigma_{i-1}) : (\sigma_i - \sigma_{i-1}) \\
\leq (f_i - f_{i-1}, w_i - w_{i-1}) + \int_{\Omega} \varepsilon(u_i^{\text{Dir}} - u_{i-1}^{\text{Dir}}) : (\sigma_i - \sigma_{i-1}). \tag{5.8}
\]
Now, for every $w \in V$, we have (see (4.5)) $\int_{\Omega} \varepsilon(w) = 0$, and therefore, by means of Poincaré’s
\[
\|\varepsilon(w_i - w_{i-1})\|_{L^2(\Omega; \mathbb{R}^{3 \times 3})} \leq c \|\varepsilon(w_i - w_{i-1})\|_{L^2(\Omega; \mathbb{R}^{3 \times 3})}
\]
and Korn’s inequality (2.1), we get
\[
\|w_i - w_{i-1}\|_V \leq c \|\varepsilon(w_i - w_{i-1})\|_{L^2(\Omega; \mathbb{R}^{3 \times 3})}. \tag{5.9}
\]
Moreover, due to (5.4) we readily check that
\[
|\xi_i - \xi_{i-1}| = \inf_{x \in K(F(\sigma_i))} |x - \xi_{i-1}| \leq c|\sigma_i - \sigma_{i-1}|. \tag{5.10}
\]
Therefore, by using (5.9) and (5.10), from (5.8) we get
\[
\|w_i - w_{i-1}\|_V^2 + \|\xi_i - \xi_{i-1}\|_{L^2(\Omega)}^2 + \|\sigma_i - \sigma_{i-1}\|_{L^2(\Omega; \mathbb{R}^{3 \times 3})}^2 \\
\leq c(\|f_i - f_{i-1}\|_{V^*}^2 + \|\varepsilon(u_i^{\text{Dir}} - u_{i-1}^{\text{Dir}})\|_{L^2(\Omega; \mathbb{R}^{3 \times 3})}^2).
\]
Now, dividing this last estimate by $\tau$ and summing for $i = 1$ to $N$, we immediately get
\[
\|u_i^\tau\|_{L^2(0,T;V)}^2 + \|\xi_i^\tau\|_{L^2(0,T;L^2(\Omega))}^2 + \|\sigma_i^\tau\|_{L^2(0,T;L^2(\Omega; \mathbb{R}^{3 \times 3}))}^2 \\
\leq c(\|f_i^\tau\|_{L^2(0,T;V^*)}^2 + \|\varepsilon(\partial_t u_i^{\text{Dir}})\|_{L^2(0,T;L^2(\Omega; \mathbb{R}^{3 \times 3}))}^2).
\]
An easy calculation yields
\[
\|f_i^\tau\|_{L^2(0,T;V^*)} \leq \|f_i\|_{L^2(0,T;V^*)},
\]
\[
\|\varepsilon(\partial_t u_i^{\text{Dir}})\|_{L^2(0,T;L^2(\Omega; \mathbb{R}^{3 \times 3}))} \leq \|\varepsilon(\partial_t u_i^{\text{Dir}})\|_{L^2(0,T;L^2(\Omega; \mathbb{R}^{3 \times 3}))},
\]
for every $\tau$. In particular, we have that
\[
f_j \to f \quad \text{strongly in } H^1(0,T;V^*),
\]
\[
\varepsilon(\partial_t u_j^{\text{Dir}}) \to \varepsilon(\partial_t u^{\text{Dir}}) \quad \text{strongly in } L^2(0,T;L^2(\Omega; \mathbb{R}^{3 \times 3})),
\]
as \( \tau \to 0 \). Now, since \( \xi_i \in [0,1] \) almost everywhere in \( \Omega \) and
\[
\sigma_i = C\varepsilon(w_i + u_i^\text{Dir}) - \xi_i C\eta_i \quad \text{a.e. in } \Omega,
\]
for \( i = 1, \ldots, N \), where \( \eta_i \in \partial F(\sigma_i) \) almost everywhere in \( \Omega \), then it is easy to see that we have
\[
\|\xi_\tau\|_{L^\infty(Q)} \leq c, \quad \|\sigma_\tau\|_{L^\infty([0,T];L^2(\Omega;\mathbb{R}^{3\times3}_{\text{sym}}))} \leq c.
\]
Eventually, by combining all the above estimates, we get
\[
\|w_\tau\|_{H^1([0,T];V)} + \|\xi_\tau\|_{H^1([0,T];L^2(\Omega))} + \|\sigma_\tau\|_{H^1([0,T];L^2(\Omega;\mathbb{R}^{3\times3}_{\text{sym}}))} \leq c. \quad (5.11)
\]

### 5.2. Extraction of strongly converging subsequences

From estimate (5.11) we deduce that there exists \( w \in H^1([0,T];V) \) such that, up to a not relabeled subsequence, we have
\[
w_\tau \rightharpoonup w \quad \text{weakly in } \ H^1([0,T];V).
\]
By exploiting the compact embedding \( H^1([0,T];V) \subset C([0,T];W) \) we have
\[
\varepsilon(w_\tau) \rightharpoonup \varepsilon(w) \quad \text{strongly in } \ C([0,T];L^2(\Omega;\mathbb{R}^{3\times3}_{\text{sym}})),
\]
\[
\varepsilon(\pi_\tau) \rightharpoonup \varepsilon(w) \quad \text{strongly in } \ L^\infty([0,T];L^2(\Omega;\mathbb{R}^{3\times3}_{\text{sym}})).
\]

We now show that there exists \( \xi \in H^1([0,T];L^2(\Omega)) \) such that, up to some not relabeled subsequence, we have
\[
\xi_\tau \rightharpoonup \xi \quad \text{strongly in } \ C([0,T];L^2(\Omega)). \quad (5.13)
\]
Indeed, (5.11) yields the existence of a \( \xi \in H^1([0,T];L^2(\Omega)) \) such that \( \xi_\tau \rightharpoonup \xi \) weakly in \( H^1([0,T];L^2(\Omega)) \) and (5.13) follows immediately once we prove that \( \xi_\tau \) is a Cauchy sequence in \( C([0,T];L^2(\Omega)) \). Let us first introduce some notation by defining
\[
K_\tau = \hat{K}(\varepsilon(\pi_\tau) + \pi_\tau^D).
\]
Now relation (5.4) can be rewritten in the more compact form
\[
\xi_\tau' + \partial I_{K_\tau}(\xi_\tau) \geq 0 \quad \text{a.e. in } Q. \quad (5.15)
\]
In particular, we have that
\[
\xi_\tau((\xi_\tau - v_\tau) = \xi_\tau(\zeta_\tau - v_\tau) + \xi_\tau(\xi_\tau - \zeta_\tau) \leq 0 \quad \text{a.e. in } Q, \quad \forall v_\tau \in K_\tau \quad \text{a.e. in } Q.
\]
Hence, we get, for every \( \delta, \tau > 0 \),
\[
\xi_\tau((\xi_\tau - \Pi_{K_\tau}(\xi_\delta)) \leq 0, \quad \xi_\tau'(\xi_\delta - \Pi_{K_\tau}(\xi_\tau)) \leq 0 \quad \text{a.e. in } Q,
\]
where \( \Pi_{K_\tau} \) denotes the projection operator onto the convex \( K_\tau \). In particular, one obtains
\[
(\xi_\delta - \xi_\tau)(\xi_\tau - \xi_\delta) \leq -\xi_\tau'(\xi_\delta - \Pi_{K_\tau}(\xi_\delta)) - \xi_\delta'(\xi_\tau - \Pi_{K_\tau}(\xi_\tau))
\]
and, integrating over $\Omega \times (0,t)$ for $t \in [0,T]$, we deduce that
\[
\frac{1}{2} \left\| \xi (t) - \xi (0) \right\|_{L^2(\Omega)}^2 \leq \int_Q \left( |\xi'| + |\xi''| \right) d\beta(K_{\tau},K_{\delta}).
\]
By extracting some not relabeled pointwise converging subsequence from $\overline{\sigma}_\tau$ we easily deduce
\[
\int_{\Omega} d\beta(K_{\tau},K_{\delta}) \to 0 \quad \text{as} \quad \tau,\delta \to 0.
\]
In the latter we have also used the fact that
\[
\varepsilon(\overline{\sigma}_\tau^{\text{Dir}}) \to \varepsilon(u^{\text{Dir}}) \quad \text{in} \quad L^\infty(0,T;H^1(\Omega;\mathbb{R}^{3\times 3}_{\text{sym}})).
\]
We have hence proved that
\[
\|\xi_{\tau} - \xi_\delta\|_{C([0,T];L^2(\Omega)))} \to 0 \quad \text{as} \quad \tau,\delta \to 0,
\]
so that $\xi_{\tau}$ is a Cauchy sequence in $C([0,T];L^2(\Omega))$. Moreover, we clearly have that
\[
\xi_{\tau} \to \xi \quad \text{strongly in} \quad L^\infty(0,T;L^2(\Omega)),
\]
as well.

Finally, it remains to show that there exists $\sigma \in H^1(0,T;L^2(\Omega;\mathbb{R}^{3\times 3}_{\text{sym}}))$ such that, up to a not relabeled subsequence, we have
\[
\sigma_{\tau},\overline{\sigma}_{\tau} \to \sigma \quad \text{strongly in} \quad L^\infty(0,T;L^2(\Omega;\mathbb{R}^{3\times 3}_{\text{sym}})).
\]
Indeed, our estimates yield
\[
\sigma_{\tau} \rightharpoonup \sigma \quad \text{weakly in} \quad H^1(0,T;L^2(\Omega;\mathbb{R}^{3\times 3}_{\text{sym}})),
\]
and we need to check that $\overline{\sigma}_{\tau}$ is a Cauchy sequence in $L^\infty(0,T;L^2(\Omega;\mathbb{R}^{3\times 3}_{\text{sym}}))$. We can write
\[
\int_{\Omega} (\mu D(\overline{\sigma}_{\tau}) \cdot D(v) + \overline{\sigma}_{\tau} : \varepsilon(v) = \langle \bar{f},v \rangle \quad \forall \ v \in V, \ a.e. \ in \ (0,T), \ (5.18)
\]
\[
L\overline{\sigma}_{\tau} + \xi_\tau \partial F(\overline{\sigma}_{\tau}) \ni \varepsilon(\overline{\sigma}_{\tau} + \overline{\sigma}_{\tau}^{\text{Dir}}) \quad a.e. \ in \ Q. \quad (5.19)
\]
By arguing similarly with respect to the proof of Theorem 4.1 (see estimate (4.13)), we easily deduce that
\[
\mu \|D(\overline{\sigma}_{\tau} - \overline{\sigma}_\delta)\|_{L^2(\Omega;\mathbb{R}^{3\times 3}_{\text{sym}})} + c\|\overline{\sigma}_{\tau} - \overline{\sigma}_\delta\|_{L^2(\Omega;\mathbb{R}^{3\times 3}_{\text{sym}})} \leq \frac{1}{c} \|\xi_{\tau} - \xi_\delta\|_{L^2(\Omega)}.
\]

5.3. Passage to the limit

We now prove that the triplet $(w,\sigma,\xi)$ solves the Quasistatic Evolution Problem.

From the convergence (5.12) we deduce
\[
D(\overline{\sigma}_{\tau}) \to D(\overline{\sigma}) \quad \text{weakly in} \quad H^1(0,T;L^2(\Omega;\mathbb{R}^{3\times 3}_{\text{sym}})),
\]
\[
D(\overline{\sigma}_{\tau}) \to D(\overline{\sigma}) \quad \text{weakly in} \quad L^2(0,T;L^2(\Omega;\mathbb{R}^{3\times 3}_{\text{sym}})).
\]
Hence, the equilibrium relation (3.7) follows. The constitutive relation (3.8) is obtained by simply passing to the limit in its discrete counterpart (5.19). For the proof of the dynamics (3.9), we first introduce the generalized play operator $\mathcal{P}$ such that $\xi(t) = \mathcal{P}[\varepsilon; \xi_0](t)$, for every $t \in [0, T]$, where $\xi$ solves
\[
\dot{\xi} + \partial R(\xi) \ni 0, \quad \xi(0) = \xi_0. \tag{5.20}
\]
This mapping is Lipschitz continuous from $L^2(\Omega; C([0, T]; \mathbb{R}^{3 \times 3}_{\text{sym}})) \times [0, 1]$ to $L^2(\Omega; C([0, T]))$ with a Lipschitz constant given in terms of the Lipschitz constants of $\hat{\lambda}_i(\varepsilon)$, $\hat{\lambda}_u(\varepsilon)$ (see Visintin [53]). Now, setting $\varepsilon_\tau := \varepsilon(\omega_\tau)$, relation (5.15) yields
\[
\xi_\tau(t_i) \in \tilde{K}(\varepsilon_\tau(t_i)), \quad \dot{\xi}_\tau(t_i)(\xi_\tau(t_i) - v) \leq 0 \quad \forall v \in \tilde{K}(\varepsilon_\tau(t_i))
\]
and therefore we have
\[
\xi_i = \xi_\tau(t_i) = \mathcal{P}[\varepsilon_\tau; \xi_0](t_i) = \dot{\xi}_\tau(t) \quad \forall t \in (t_{i-1}, t_i].
\]
Using this, and also the fact that $\mathcal{P}$ is bounded also from $L^2(\Omega; H^1(0, T; \mathbb{R}^{3 \times 3}_{\text{sym}})) \times [0, 1]$ to $L^2(\Omega; H^1(0, T))$, it is easy to prove that
\[
\|\dot{\xi}_\tau - \mathcal{P}[\varepsilon_\tau; \xi_0]\|_{L^2(0, T; L^2(\Omega))] \leq C_T.
\]
Now observe that we have
\[
H^1(0, T; H^1(\Omega; \mathbb{R}^{3 \times 3}_{\text{sym}})) = H^1(\Omega; H^1(0, T; \mathbb{R}^{3 \times 3}_{\text{sym}})) \subset L^2(\Omega; C([0, T]; \mathbb{R}^{3 \times 3}_{\text{sym}})),
\]
with compact embedding, and therefore estimate (5.11) also implies that, up to a subsequence
\[
\varepsilon_\tau \to \varepsilon \quad \text{strongly in } L^2(\Omega; C([0, T]; \mathbb{R}^{3 \times 3}_{\text{sym}})),
\]
where $\varepsilon := \varepsilon(\omega)$. Hence, by means of this last convergence, of the strong convergence (5.17) and of the above-mentioned Lipschitz continuity property of $\mathcal{P}$, by passing to the limit as $\tau \to 0$ we conclude that
\[
\xi = \mathcal{P}[\varepsilon; \xi_0]
\]
which means that $\xi$ and $\varepsilon$ solve (5.20) and the dynamics (3.9) of the single-variant volume fraction $\xi$ follows.
