

SRT Addendum: Accelerations

DBW

March 18, 2017

In this very short note you will find the following derivation: If an object X experiences some force F' and hence undergoes some acceleration a' , then an observer O sees the following parallel and perpendicular accelerations a_{\parallel} and a_{\perp} given by:

$$a'_{\perp} = \gamma^2 a_{\perp}, \quad a'_{\parallel} = \gamma^3 a_{\parallel},$$

where $\gamma = \frac{1}{\sqrt{1-\beta^2}}$ is the usual Lorentz factor.

We take K' to be an instantaneous rest frame for the object X , and the coordinates in K' are primed. K' is chosen to coincide at time $t' = 0$ with the object X . K is the rest frame of an observer, which we also take to coincide with K' at time $t = 0$ – the coordinates in K are unprimed. In K the object has a velocity v in the x -direction at time $t = 0$. We thus have the following transformation rules between K' and K :

$$x' = \gamma(x - \beta t), \quad y' = y, \quad z' = z, \quad t' = \gamma(t - \beta x).$$

We work in units such that $c = 1$, and thus replace v by β . Later we can restore units by putting $\beta = v/c$ and $t \mapsto ct$. Let us first consider the case in which the acceleration a' is in the x -direction. Then X follows a trajectory $x' = \frac{1}{2}a't'^2$ in K' . Inserting the expressions for x' and t' one arrives at the following quadratic equation for x :

$$a'\gamma\beta^2 \cdot x^2 - 2(1 + a'\gamma\beta) \cdot x + a'\gamma t^2 + 2\beta t = 0.$$

Calculating the discriminant one finds $D = 4(1 + 2a'\gamma\beta t(1 - \beta^2)) = 4(1 + 2\frac{a't\beta}{\gamma})$.

Therefore we find

$$x = \frac{1 + a'\gamma\beta t \pm \sqrt{1 + \frac{2a'\beta t}{\gamma}}}{a'\gamma\beta}.$$

In order to recover $x = 0$ at $t = 0$, we need the minus sign in the solution for x , so we only have one solution. Writing out to second order in t we find

$$x = \beta t + \frac{1}{2} \cdot \frac{a'}{\gamma^3} \cdot t^2 + O(t^3),$$

in which we recognize the linear motion of K' $x = \beta t$ and the second order contains the acceleration a in the frame K : $a = \frac{a'}{\gamma^3}$. This proves the second of the identities to be proven.

Now consider the motion $y' = \frac{1}{2}b't'^2$. Putting in the expressions for y' and t' from the Lorentz transformations we find

$$y = \frac{b'}{2}\gamma^2(t - \beta x)^2.$$

Now we put in the previous expression for x but, as we are only interested in second order contributions, we may safely put $x = \beta t + O(t^2)$, and thus find

$$y = \frac{b'}{2}\gamma^2 t^2 (1 - \beta^2)^2 + O(t^3).$$

Since $1 - \beta^2 = \gamma^{-2}$ we find

$$y = \frac{b'}{2}\gamma^{-2} t^2 + O(t^3).$$

Reading of, we see $a_{\perp} = \frac{b'}{\gamma^2}$, but $b' = a'_{\perp}$ and thus both equations follow.

The use of these formulae is for example in extending the Larmor formula for the power radiated by a nonrelativistic accelerating charged particle to a relativistic particle. Larmor's formula states that the radiated power P radiated by a charged accelerating particle is given by a formula of the form $P = ka^3$. Since this formula only holds for $\beta \ll 1$ it can be extended by using this formula to obtain the power P in the instantaneous rest frame K' and using that $P' = P$, since the energies dW and dW' transform in the same way as the time intervals dt and dt' . Then one uses $P = P' = ka'^3 = k(a'_{\perp}{}^2 + a'_{\parallel}{}^2) = k\gamma^4(a_{\perp}^2 + \gamma^2 a_{\parallel}^2)$. Furthermore

$$a_{\perp}^2 + \gamma^2 a_{\parallel}^2 = \gamma^2(a_{\perp}^2 + a_{\parallel}^2 - (\gamma^2 - 1)a_{\perp}^2) = \gamma^2(a^2 - \beta^2 a_{\perp}^2)$$

and $a_{\perp}^2 = \frac{(\mathbf{a} \times \boldsymbol{\beta})^2}{\beta^2}$ resulting in

$$P = k\gamma^6(a^2 - (\mathbf{a} \times \boldsymbol{\beta})^2).$$
