Abstract

We study ground state, symmetric state and central vortex states, as well as their energy and chemical potential diagrams, in rotating Bose-Einstein condensates (BEC) analytically and numerically. As preparatory steps, we take the three-dimensional (3D) Gross-Pitaevskii equation (GPE) with an angular momentum rotation term, scale it to obtain a four-parameter model, reduce it to a 2D GPE in the limiting regime of strong anisotropic confinement and present its semiclassical scaling and geometrical optics. We prove existence of the ground state in a simple but mathematically rigorous way when the angular rotation speed $|\Omega|$ is less than the minimal trapping frequency in the $xy$ plane $\omega_{xy} := \min\{\omega_x, \omega_y\}$. Nonexistence of the ground state is proven for $|\Omega|$ larger than $\omega_{xy} := \max\{\omega_x, \omega_y\}$. We find that symmetric and central vortex states are independent of the angular rotational momentum. We perform numerical experiments computing these states using a continuous normalized gradient flow (CNGF) method with a backward Euler finite difference (BEFD) discretization. We test several ways to choose initial data for the CNGF and its BEFD discretization to compute ground state numerically and find only one choice which always gives the ground state for all $|\Omega| < \omega_{xy}$ in an isotropic trap. Ground state, symmetric state and central vortex states, as well as their energy configurations, are reported in 2D and 3D for rotating BEC. Through our numerical study, we find various configurations with several vortices in both 2D and 3D structures. Finally we report the critical
angular velocity $\Omega^c$ at which the ground state loses symmetry, numerical verification of dimension reduction from 3D to 2D, errors for the Thomas-Fermi (TF) approximation, and spurious numerical ground states when $|\Omega| > \omega^{xy}$.

Key Words: rotating Bose-Einstein condensate, Gross-Pitaevskii equation, ground state, symmetric state, central vortex state, angular momentum rotation, continuous normalized gradient flow, energy, chemical potential.

1 Introduction

Since its realization in dilute bosonic atomic gases [4, 10], Bose-Einstein condensation (BEC) of alkali atoms and hydrogen has been produced and studied extensively in the laboratory [34, 38], and has permitted an intriguing glimpse into the macroscopic quantum world. In view of potential applications [22], the study of quantized vortices, which are related to superfluid properties, is one of the key issues. In fact, bulk superfluids are distinguished from normal fluids by their ability to support dissipationless flow. Such persistent currents are intimately related to the existence of quantized vortices, which are localized phase singularities with integer topological charge [22]. The superfluid vortex is an example of a topological defect that is well known in superconductors [30] and in liquid helium [18]. The occurrence of quantized vortices in superfluids has been the focus of fundamental theoretical and experimental work [18]. Different groups have obtained quantized vortices experimentally, e.g. the JILA group [34], the ENS group [33, 39] and the MIT group [38]. Currently, there are at least two typical ways to generate quantized vortices from BEC ground state: (i) impose a laser beam rotating with an angular velocity $\Omega$ on the magnetic trap holding the atoms to create a harmonic anisotropic potential [42], (ii) add to the stationary magnetic trap a narrow, moving Gaussian potential, representing a far-blue-detuned laser [28]. In fact, recent experimental and theoretical advances in exploration of quantized vortices in BEC have spurred great excitement in the atomic physics community and renewed interest in studying superfluidity.

The properties of a BEC in a rotational frame at temperatures $T$ much smaller than the critical condensation temperature $T_c$ are usually well modelled by a nonlinear Schrödinger equation (NLSE) for the macroscopic wave function known as the Gross-Pitaevskii equation (GPE) [36], which incorporates the trap potential, rotational frame, as well as the interactions among the atoms. The effect of the interactions is described by a mean field which leads to a nonlinear term in the GPE. The cases of repulsive and attractive interactions - which can both be realized in the experiment - correspond to defocusing and focusing nonlinearities in the GPE, respectively.

There has been a series of recent numerical studies for the stability and dynamics of quantized vortices in BEC. For non-rotating BEC, Bao and Du [6] presented a CNGF with BEFD discretization to compute central vortex states, Caradoc-Davis et. al [12, 13], Bao and Zhang [9] studied stability of central vortices and their
interactions numerically, Lundh et. al [32] studied free expansion of vortex state. For rotating BEC, in the line of adding a far-blue-detuned Gaussian laser stirrer, Caradoc-Davis et. al [12, 13], Jackson et. al [27, 28], and Bao et. al [7, 5] studied dynamics of vortices, generation of vortices from the ground state and critical angular speed; in the line of BEC in a rotational frame, Aftalion and Du [1], Aftalion and Riviere [2] studied numerically and asymptotically ground state, critical angular velocity and energy diagram in the Thomas-Fermi (TF) or semiclassical regime, Aftalion and Danaila [3] and Modugno et. al [35] reported bent vortices, e.g. S-shaped vortex and U-shaped vortex, numerically in cigar-shaped condensation and compared with experimental results [39], Garcia-Ripoll and Perez-Garcia [24, 23, 26] studied stability of the central vortex, Tsubota et. al [45] reported vortex lattice formation. Moreover, Svidzinsky and Fetter [42] have studied dynamics of a vortex line depending on its curvature. For more numerical and theoretical study of quantized vortices, we refer to the review articles [22] and a recent book [37].

The aim of this paper is to analytically and numerically study the ground state, symmetric state and central vortex states, as well as their energy diagrams in BEC under a rotational frame representing a laser beam rotating with an angular velocity $\Omega$ on the magnetic trap. We extend the efficient and stable numerical method of CNGF with BEFD discretization, proposed in [6] for computing ground state of non-rotating BEC, to rotating BEC, and then apply it to study the ground state, symmetric state, central vortex states, central vortex ground state, as well as their energy diagrams, in rotating BEC numerically. Vortices and energy bifurcation are observed in the ground state when the angular rotation speed $|\Omega|$ is bigger than a critical frequency $\Omega^*$. These results agree very well with those, obtained by other numerical methods, in the physical literatures. Furthermore, we also present some new analytical and numerical results for the ground state, symmetric state and central vortex states, as well as their energy diagrams in rotating BEC. These results include: (i) prove in a simple but mathematically rigorous way for existence of the ground state when the angular rotation speed $|\Omega|$ is less than the minimal trapping frequency in $xy$ plane $\omega_{xy} = \min\{\omega_x, \omega_y\}$, and resp., nonexistence of the ground state when $|\Omega|$ is bigger than the maximal trapping frequency $\omega_{xy} = \max\{\omega_x, \omega_y\}$; (ii) provide asymptotics of the energy and chemical potential of the ground state in the semiclassical regime; (iii) show that the ground state is a global minimizer of the energy functional over the unit sphere and all excited states are saddle points in linear case; (iv) provide semiclassical scaling and geometrical optics for rotating BEC; (v) find numerically the ratio between energies of different stationary states goes to constant in the semiclassical regime; (vi) find the asymptotics of the energy of the ground state when $|\Omega|$ is near $\omega_{xy}$; (vii) do numerical verification for dimension reduction from 3D to 2D and find convergence rate; (viii) define the central vortex ground state and find critical rotation speed $\Omega^*$ for it numerically; (ix) study the TF approximation numerically; (x) test different choices of initial data for the numerical method in an isotropic trap and find there is only one choice which always guarantee to get the ground state for $0 \leq |\Omega| < \omega_{xy}$. 

3
The paper is organized as follows. In section 2, we take the 3D GPE with an angular momentum term, scale it to get a four parameter model, reduce it to a 2D problem in a limiting regime, and present its semiclassical scaling and geometrical optics. In section 3, we study the energy functional and show existence of ground state when the angular speed $|\Omega| < \omega_{xy}$, and resp., nonexistence of the ground state when $|\Omega| > \omega_{xy}$. In section 4, we present the symmetric state, central vortex states and central vortex ground state. In section 5, we extend the CNGF and its BEFD discretization, proposed for non-rotating BEC in [6], to rotating BEC for computing ground state and vortex states. In section 6, we report numerical results in 2D and 3D, and finally in section 7 we draw some conclusions.

## 2 GPE in a rotational frame

At temperatures $T$ much smaller than the critical temperature $T_c$ [30], a BEC in a rotational frame is well described by the macroscopic wave function $\psi(x, t)$, whose evolution is governed by a self-consistent, mean field nonlinear Schrödinger equation known as the Gross-Pitaevskii equation (GPE) with an angular momentum rotational term [1, 11, 20, 24], w.r.o.g. assuming the rotation being around the $z$-axis:

$$i\hbar \frac{\partial \psi(x, t)}{\partial t} = \frac{\delta E(\psi)}{\delta \psi^*} := H \psi$$

$$= \left( -\frac{\hbar^2}{2m} \nabla^2 + V(x) + NU_0|\psi(x, t)|^2 - \Omega L_z \right) \psi(x, t),$$

(2.1)

where $x = (x, y, z)^T \in \mathbb{R}^3$ is the spatial coordinate vector, $m$ is the atomic mass, $\hbar$ is the Planck constant, $N$ is the number of atoms in the condensate, $\Omega$ is an angular velocity, $V(x)$ is an external trapping potential. When a harmonic trap potential is considered, $V(x) = \frac{m}{2} \left( \omega_x^2 x^2 + \omega_y^2 y^2 + \omega_z^2 z^2 \right)$ with $\omega_x$, $\omega_y$ and $\omega_z$ being the trap frequencies in $x$-, $y$- and $z$-direction respectively. For the following we assume (w.r.o.g) $\omega_x \leq \omega_y$. $U_0 = \frac{4\pi\hbar^2 a_s}{m}$ describes the interaction between atoms in the condensate with the $s$-wave scattering length $a_s$ (positive for repulsive interaction and negative for attractive interaction) and

$$L_z = xp_y - yp_x = -i\hbar \left( x\partial_y - y\partial_x \right)$$

(2.2)

is the $z$-component of the angular momentum $L = x \times P$ with the momentum operator $P = -i\hbar \nabla = (px, py, pz)^T$. The energy functional per particle $E(\psi)$ is defined as

$$E(\psi) = \int_{\mathbb{R}^3} \left[ \frac{\hbar^2}{2m} |\nabla \psi|^2 + V(x)|\psi|^2 + \frac{NU_0}{2} |\psi|^4 - \Omega \psi^* L_z \psi \right] dx.$$

(2.3)

Here we use $f^*$ denotes the conjugate of a function $f$. It is convenient to normalize the wave function by requiring

$$\int_{\mathbb{R}^3} |\psi(x, t)|^2 \ dx = 1.$$  

(2.4)
2.1 Dimensionless GPE in a rotational frame

By introducing the dimensionless variables: \( t \rightarrow t/\omega_m \) with \( \omega_m = \min\{\omega_x, \omega_y, \omega_z\} \), \( x \rightarrow xa_0 \) with \( a_0 = \sqrt{\hbar/m\omega_m} \), \( \psi \rightarrow \psi/a_0^{3/2} \), \( \Omega \rightarrow \Omega\omega_m \) and \( E(\cdot) \rightarrow \hbar\omega_mE_{\beta, \Omega}(\cdot) \), we get the dimensionless GPE

\[
i \frac{\partial \psi(x, t)}{\partial t} = \frac{\delta E_{\beta, \Omega}(\psi)}{\delta \psi^*} := H \psi
\]

where \( \beta = \frac{L_0 N}{a_0^3 \omega_m} = \frac{4\pi a_0 N}{a_0^3 \omega_m} \), \( L_z = -i(x\partial_y - y\partial_x) \), \( V(x) = \frac{1}{2} \left( \gamma_x^2 x^2 + \gamma_y^2 y^2 + \gamma_z^2 z^2 \right) \) with \( \gamma_x = \frac{\omega_x}{\omega_m}, \gamma_y = \frac{\omega_y}{\omega_m}, \) and \( \gamma_z = \frac{\omega_z}{\omega_m} \), and the dimensionless energy functional per particle \( E_{\beta, \Omega}(\psi) \) is defined as

\[
E_{\beta, \Omega}(\psi) = \int_{\mathbb{R}^3} \left[ \frac{1}{2} \left| \nabla \psi(x, t) \right|^2 + V(x)|\psi|^2 + \frac{\beta}{2} |\psi|^4 - \Omega \psi^* L_z \psi \right] dx.
\]

In a disk-shaped condensation with parameters \( \omega_x \approx \omega_y \) and \( \omega_z \gg \omega_x \) \( \iff \gamma_x = 1, \gamma_y \approx 1 \) and \( \gamma_z \gg 1 \) with choosing \( \omega_m = \omega_x \), the 3D GPE (2.5) can be reduced to a 2D GPE with \( x = (x, y)^T \) [7, 5, 8]:

\[
i \frac{\partial \psi(x, t)}{\partial t} = -\frac{1}{2} \nabla^2 \psi + V_2(x, y)\psi + \beta_2 |\psi|^2 \psi - \Omega L_z \psi,
\]

where \( \beta_2 \approx \beta_2^* = \beta \frac{\gamma_z}{2\pi} \) and \( V_2(x, y) = \frac{1}{2} \left( \gamma_x^2 x^2 + \gamma_y^2 y^2 \right) \) [1, 7, 8]. Thus here we consider the dimensionless GPE in a rotational frame in \( d \)-dimensions (\( d = 2, 3 \)):

\[
i \frac{\partial \psi(x, t)}{\partial t} = -\frac{1}{2} \nabla^2 \psi + V_d(x)\psi + \beta_d |\psi|^2 \psi - \Omega L_z \psi, \quad x \in \mathbb{R}^d, \quad t \geq 0,
\]

where \( \beta_3 = \beta \) and \( V_d(x, y, z) = V(x, y, z) \).

Two important invariants of (2.8) are the normalization of the wave function

\[
N(\psi) = \int_{\mathbb{R}^d} |\psi(x, t)|^2 \, dx \equiv \int_{\mathbb{R}^d} |\psi(x, 0)|^2 \, dx = 1, \quad t \geq 0
\]

and the energy

\[
E_{\beta, \Omega}(\psi) = \int_{\mathbb{R}^d} \left[ \frac{1}{2} \left| \nabla \psi(x, t) \right|^2 + V_d(x)|\psi|^2 + \frac{\beta_d}{2} |\psi|^4 - \Omega \psi^* L_z \psi \right] dx.
\]

2.2 Stationary states

To find a stationary solution of (2.8), we write

\[
\psi(x, t) = e^{-i\mu t}\phi(x),
\]

(2.11)
where $\mu$ is the chemical potential of the condensate and $\phi$ is independent of time. Inserting (2.11) into (2.8) gives the following equation for $\phi(x)$

$$\mu \phi(x) = -\frac{1}{2} \Delta \phi(x) + V_d(x) \phi(x) + \beta_d |\phi(x)|^2 \phi(x) - \Omega L_z \phi(x), \quad x \in \mathbb{R}^d,$$  \hspace{1cm} (2.12)

under the normalization condition

$$\|\phi\|^2 = \int_{\mathbb{R}^d} |\phi(x)|^2 \, dx = 1. \hspace{1cm} (2.13)$$

This is a nonlinear eigenvalue problem with a constraint and any eigenvalue $\mu$ can be computed from its corresponding eigenfunction $\phi$ by

$$\mu = \mu_{\beta,\Omega}(\phi) = \int_{\mathbb{R}^d} \left[ \frac{1}{2} |\nabla \phi(x)|^2 + V_d(x) |\phi(x)|^2 + \beta_d |\phi(x)|^4 - \Omega \phi^*(x) L_z \phi(x) \right] \, dx$$  
$$= E_{\beta,\Omega}(\phi) + \int_{\mathbb{R}^d} \frac{\beta_d}{2} |\phi(x)|^4 \, dx. \hspace{1cm} (2.14)$$

In fact, the eigenfunctions of (2.12) under the constraint (2.13) are the critical points of the energy functional $E_{\beta,\Omega}(\phi)$ over the unit sphere $S = \{ \phi \in \mathbb{C} \mid \|\phi\| = 1, E_{\beta,\Omega}(\phi) < \infty \}$. Furthermore (2.12) is the Euler-Lagrange equation of the energy functional (2.10) with $\psi = \phi$ under the constraint (2.13).

### 2.3 Semiclassical scaling and geometrical optics

When $\beta_d \gg 1$, i.e. in a strongly repulsive interacting condensation or in semiclassical regime, another scaling (under the normalization (2.9) with $\beta = \beta^*$) for the GPE (2.8) is also very useful in practice by choosing $x \to \varepsilon^{-1/2} x$ and $\psi = \psi^{\varepsilon} \varepsilon^{d/4}$ with $\varepsilon = \beta_d^{-2/(d+2)}$.

$$i\varepsilon \frac{\partial \psi^{\varepsilon}(x,t)}{\partial t} = \frac{\delta E_{\varepsilon,\Omega}(\psi^{\varepsilon})}{\delta (\psi^{\varepsilon})^*} := H^{\varepsilon} \psi^{\varepsilon}$$  
$$= -\frac{\varepsilon^2}{2} \nabla^2 \psi^{\varepsilon} + V_d(x) \psi^{\varepsilon} + |\psi^{\varepsilon}|^2 \psi^{\varepsilon} - \varepsilon \Omega L_z \psi^{\varepsilon}, \quad x \in \mathbb{R}^d, \hspace{1cm} (2.15)$$

where the energy functional $E_{\varepsilon,\Omega}(\psi^{\varepsilon})$ is defined as

$$E_{\varepsilon,\Omega}(\psi^{\varepsilon}) = \int_{\mathbb{R}^d} \left[ \frac{\varepsilon^2}{2} |\nabla \psi^{\varepsilon}|^2 + V_d(x)|\psi^{\varepsilon}|^2 + \frac{1}{2} |\psi^{\varepsilon}|^4 - \varepsilon \Omega (\psi^{\varepsilon})^* L_z \psi^{\varepsilon} \right] \, dx = O(1),$$

assuming that $\psi^{\varepsilon}$ is $\varepsilon$-oscillatory and ‘sufficiently’ integrable such that all terms have $O(1)$-integral. Similarly, the nonlinear eigenvalue problem (2.12) (under the normalization (2.13) with $\phi = \phi^{\varepsilon}$) reads

$$\mu^{\varepsilon} \phi^{\varepsilon}(x) = -\frac{\varepsilon^2}{2} \Delta \phi^{\varepsilon} + V_d(x) \phi^{\varepsilon} + |\phi^{\varepsilon}|^2 \phi^{\varepsilon} - \varepsilon \Omega L_z \phi^{\varepsilon}, \quad x \in \mathbb{R}^d, \hspace{1cm} (2.16)$$
where any eigenvalue $\mu^\varepsilon$ can be computed from its corresponding eigenfunction $\phi^\varepsilon$ by

$$
\mu^\varepsilon = \mu_{\varepsilon,\Omega}(\phi^\varepsilon) = \int_{\mathbb{R}^d} \left[ \frac{\varepsilon^2}{2} |\nabla \phi^\varepsilon|^2 + V_0(x)|\phi^\varepsilon|^2 + |\phi^\varepsilon|^4 - \varepsilon\Omega(\psi^\varepsilon)^* L_z \psi^\varepsilon \right] \, dx = O(1).
$$

Furthermore it is easy to get the leading asymptotics of the energy functional $E_{\beta,\Omega}(\psi)$ in (2.10) and the chemical potential $\mu_{\beta,\Omega}(\phi)$ in (2.14) when $\beta_d \gg 1$ from this scaling:

$$
E_{\beta,\Omega}(\psi) = \varepsilon^{-1} E_{\varepsilon,\Omega}(\psi^\varepsilon) = O \left( \varepsilon^{-1} \right) = O \left( \beta_d^{2/(d+2)} \right),
$$

$$
\mu_{\beta,\Omega}(\phi) = \varepsilon^{-1} \mu_{\varepsilon,\Omega}(\phi^\varepsilon) = O \left( \varepsilon^{-1} \right) = O \left( \beta_d^{2/(d+2)} \right), \quad \beta_d \gg 1.
$$

These asymptotic results will be confirmed by our numerical results in Section 6.

When $0 < \varepsilon \ll 1$, i.e. $\beta_d \gg 1$, we set

$$
\psi^\varepsilon(x, t) = \sqrt{\rho^\varepsilon(x, t)} \exp \left( \frac{i}{\varepsilon} S^\varepsilon(x, t) \right),
$$

where $\rho^\varepsilon = |\psi^\varepsilon|^2$ and $S^\varepsilon$ is the phase of the wave-function. Inserting (2.19) into (2.15) and collecting real and imaginary parts give

$$
\partial_t \rho^\varepsilon + \text{div}(\rho^\varepsilon \nabla S^\varepsilon) + \Omega(x \partial_y - y \partial_x) \rho^\varepsilon = 0,
$$

$$
\partial_t S^\varepsilon + \frac{1}{2} |\nabla S^\varepsilon|^2 + V_d(x) + \rho^\varepsilon + \Omega(x \partial_y - y \partial_x) S^\varepsilon = \frac{\varepsilon^2}{2} \frac{1}{\sqrt{\rho^\varepsilon}} \Delta \sqrt{\rho^\varepsilon}.
$$

Eq. (2.20) is the transport equation for the atom density and (2.21) the Hamilton-Jacobi equation for the phase.

By formally passing to the limit $\varepsilon \to 0$, we obtain the system

$$
\partial_t \rho^0 + \text{div}(\rho^0 \nabla S^0) + \Omega(x \partial_y - y \partial_x) \rho^0 = 0,
$$

$$
\partial_t S^0 + \frac{1}{2} |\nabla S^0|^2 + V_d(x) + \rho^0 + \Omega(x \partial_y - y \partial_x) S^0 = 0.
$$

### 3 Ground state

The ground state wave function $\phi^g(x) := \phi_{\beta,\Omega}^g(x)$ of a rotating BEC is found by minimizing the energy functional $E_{\beta,\Omega}(\phi)$ over the unit sphere $S$:

(I) Find $(\mu_{\beta,\Omega}, \phi_{\beta,\Omega}^g \in S)$ such that

$$
E^g := E_{\beta,\Omega} = E_{\beta,\Omega}(\phi_{\beta,\Omega}^g) = \min_{\phi \in S} E_{\beta,\Omega}(\phi), \quad \mu^g := \mu_{\beta,\Omega} = \mu_{\beta,\Omega}(\phi_{\beta,\Omega}^g).
$$

Any eigenfunction $\phi(x)$ of (2.12) under the constraint (2.13) whose energy $E_{\beta,\Omega}(\phi) > E_{\beta,\Omega}(\phi_{\beta,\Omega}^g)$ is usually called as an excited state in the physical literature [37].

Although existence or nonexistence of the ground state when $|\Omega| < \gamma_{xy} := \min\{\gamma_x, \gamma_y\}$ or $|\Omega| > \tau_{xy} := \max\{\gamma_x, \gamma_y\}$ respectively was pointed out in physical literatures [37, 1], these conjectures were mostly based on physical intuition, i.e. whether there exists effective trapping [37, 1]. In this section, we will present a simple but mathematically rigorous justification for this physically intuitive results by carefully study the energy functional $E_{\beta,\Omega}(\phi)$ in (2.10).
3.1 Existence of the ground state when $|\Omega| < \gamma_{xy}$

To study the existence of the ground state in rotating BEC, we first present some properties of the energy functional

**Lemma 3.1**

i) In 2D, we have

\[
E_{\beta, -\Omega}(\phi(x, -y)) = E_{\beta, \Omega}(\phi(x, y)), \quad E_{\beta, -\Omega}(\phi(-x, y)) = E_{\beta, \Omega}(\phi(x, y)), \quad \phi \in S.
\] (3.2)

ii) In 3D, we have

\[
E_{\beta, -\Omega}(\phi(x, -y, z)) = E_{\beta, \Omega}(\phi(x, y, z)), \quad E_{\beta, -\Omega}(\phi(-x, y, z)) = E_{\beta, \Omega}(\phi(x, y, z)), \quad \phi \in S.
\] (3.3)

iii) In 2D and 3D, we have

\[
\int_{\mathbb{R}^d} \left[ \frac{1 - |\Omega|}{2} |\nabla \phi(x)|^2 + \left( V_d(x) - \frac{|\Omega|}{2}(x^2 + y^2) \right) |\phi|^2 + \frac{\beta_d}{2} |\phi|^4 \right] dx \leq E_{\beta, \Omega}(\phi)
\]

\[
\leq \int_{\mathbb{R}^d} \left[ \frac{1 + |\Omega|}{2} |\nabla \phi(x)|^2 + \left( V_d(x) + \frac{|\Omega|}{2}(x^2 + y^2) \right) |\phi|^2 + \frac{\beta_d}{2} |\phi|^4 \right] dx.
\] (3.4)

**Proof:** i) From (2.10) with $\psi = \phi$ and $d = 2$, observing (2.2), with a change of variables, we have

\[
E_{\beta, -\Omega}(\phi(x, -y)) = \int_{\mathbb{R}^2} \left[ \frac{1}{2} |\nabla \phi(x, -y)|^2 + V_d(x)|\phi(x, -y)|^2 + \frac{\beta_d}{2} |\phi(x, -y)|^4 + \Omega \phi^*(x, -y) L_z \phi(x, -y) \right] dxdy
\]

\[
=\int_{\mathbb{R}^2} \left[ \frac{1}{2} |\nabla \phi(x, y)|^2 + V_d(x)|\phi(x, y)|^2 + \frac{\beta_d}{2} |\phi(x, y)|^4 - \Omega \phi^*(x, y) L_z \phi(x, y) \right] dxdy
\]

\[
= E_{\beta, \Omega}(\phi(x, y)), \quad \phi \in S.
\] (3.5)

Similarly, we obtain the second equality in (3.2).

ii) The proof is similar as in i) except $d = 3$, details are omitted.

iii) From (2.2), the H"{o}lder inequality, we have

\[
\left| \int_{\mathbb{R}^d} -\Omega \phi^*(x) L_z \phi(x) \, dx \right| \leq |\Omega| \int_{\mathbb{R}^d} |\phi^*(x) L_z \phi(x)| \, dx
\]

\[
= |\Omega| \int_{\mathbb{R}^d} |\phi^*(x)(x \partial_y \phi - y \partial_x \phi)| \, dx \leq |\Omega| \int_{\mathbb{R}^d} \left[ |x \phi^*| |\partial_y \phi| + |y \phi^*| |\partial_x \phi| \right] \, dx
\]

\[
\leq \frac{|\Omega|}{2} \int_{\mathbb{R}^d} \left[ (|\partial_x \phi|^2 + |\partial_y \phi|^2) + (x^2 + y^2)|\phi|^2 \right] \, dx.
\] (3.6)
Thus the inequality (3.4) is a combination of (3.6) and (2.10) with \( \psi = \phi \).

From this lemma, since \( \gamma_y \geq \gamma_x = \gamma_{xy} \) and \( \gamma_z > 0 \), when \( \beta_d \geq 0 \) and \( |\Omega| < \gamma_{xy} \), we know that the energy functional \( E_{\beta, \Omega}(\phi) \) is positive, coercive and weakly lower semicontinuous on \( S \). Thus the existence of a minimum follows from the standard theory [43] and we have

**Theorem 3.1**

i) In 2D, if \( \phi_{\beta, \Omega}(x, y) \in S \) is a ground state of the energy functional \( E_{\beta, \Omega}(\phi) \), then \( \phi_{\beta, \Omega}(x, -y) \in S \) and \( \phi_{\beta, \Omega}(-x, y) \in S \) are ground states of the energy functional \( E_{\beta, -\Omega}(\phi) \). Furthermore

\[
E_{\beta, \Omega}^g = E_{\beta, -\Omega}^g, \quad \mu_{\beta, \Omega}^g = \mu_{\beta, -\Omega}^g. \tag{3.7}
\]

ii) In 3D, if \( \phi_{\beta, \Omega}(x, y, z) \in S \) is a ground state of the energy functional \( E_{\beta, \Omega}(\phi) \), then \( \phi_{\beta, \Omega}(x, -y, z) \in S \) and \( \phi_{\beta, \Omega}(-x, y, z) \in S \) are ground states of the energy functional \( E_{\beta, -\Omega}(\phi) \), and (3.7) is also valid.

iii). When \( \beta_d \geq 0 \) and \( |\Omega| < \gamma_{xy} \), there exists a minimizer for the minimization problem (3.1), i.e. there exist ground state.

For understanding the uniqueness question, note that \( E_{\beta, \Omega}(\alpha \phi_{\beta, \Omega}) = E_{\beta, \Omega}(\phi_{\beta, \Omega}) \) for all \( \alpha \in \mathbb{C} \) with \( |\alpha| = 1 \). Thus an additional constraint has to be introduced to show uniqueness. For non-rotating BEC, i.e. \( \Omega = 0 \), the unique positive minimizer is usually taken as the ground state. In fact, the ground state is unique up to a constant \( \alpha \) with \( |\alpha| = 1 \), i.e. density of the ground state is unique, when \( \Omega = 0 \). For rotating BEC under \( |\Omega| < \gamma_{xy} \), in section 5, we present a CNGF and its BEFD discretization for computing a minimizer of the minimization problem (3.1) with appropriately chosen initial data. From our numerical results, the density of the ground state is no longer unique when \( |\Omega| > \gamma_{xy} \) and \( \Omega \) is a critical angular rotation speed.

### 3.2 Nonexistence of ground states when \( |\Omega| > \gamma_{xy} \)

Denote \( \gamma_r = \gamma_{xy} \) and notice \( \frac{1}{2}(\gamma_{xx} r^2 + \gamma_{yy} y^2) \leq \frac{1}{2}\gamma_r^2 r^2 \) with \( r = \sqrt{x^2 + y^2} \), we have

\[
E_{\beta, \Omega}(\phi) \leq \frac{1}{2} \int_0^{2\pi} \int_0^{\infty} \left[ |\partial_r \phi|^2 + \frac{1}{r^2} |\partial_\theta \phi|^2 + \gamma_{r}^2 r^2 |\phi|^2 + \beta_2 |\phi|^4 + 2\gamma \phi^{*} \partial_\theta \phi \right] r \, dr \, d\theta, \\
\quad \quad \quad \quad \quad \quad d = 2, \tag{3.8}
\]

\[
E_{\beta, \Omega}(\phi) \leq \frac{1}{2} \int_{-\infty}^{\infty} \int_0^{2\pi} \int_0^{\infty} \left[ |\partial_r \phi|^2 + \frac{1}{r^2} |\partial_\theta \phi|^2 + |\partial_z \phi|^2 + (\gamma_{r}^2 r^2 + \gamma_{z}^2 z^2) |\phi|^2 \right. \\
+ \left. \beta_2 |\phi|^4 + 2i \gamma \phi^{*} \partial_\theta \phi \right] r \, dr \, d\theta \, dz, \quad d = 3, \tag{3.9}
\]

where \( (r, \theta) \) and \( (r, \theta, z) \) are polar (in 2D), and resp., cylindrical coordinates (in 3D). In 2D, let

\[
\phi_m(x) = \phi_m(r, \theta) = \phi_m(r) e^{im\theta}, \quad \text{with} \quad \phi_m(r) = \frac{\gamma^{(|m|+1)/2}}{\sqrt{|m|!}} r^{|m|} e^{-\frac{\gamma_r r^2}{2}}, \tag{3.10}
\]
where $m$ is an integer. In fact, $\phi_m(x)$ is the central vortex state with winding number $m$ of the GPE (2.8) with $d = 2$, $\beta_d = 0$ and $\Omega = 0$. It is very easy to check that $\phi_m$ satisfies

$$\|\phi_m\| = 2\pi \int_0^\infty |\phi_m(r)|^2 r \, dr = 1, \quad m \in \mathbb{Z},$$

$$\left| \frac{1}{2} \left[ -\frac{1}{r} \frac{d}{dr} \left( r \frac{d}{dr} \right) + r^2 + \frac{m^2}{r^2} \right] \phi_m(r) \right| = (|m| + 1) \gamma_r \phi_m(r), \quad 0 < r < \infty. \quad (3.12)$$

Thus $\phi_m(x) \in S$ and we compute

$$E_{\beta,\Omega}(\phi_m(x)) \leq (|m| + 1) \gamma_r - \Omega m + \beta_2 \pi \int_0^\infty |\phi_m(r)|^4 r \, dr$$

$$= (|m| + 1) \gamma_r - \Omega m + \frac{\beta_2 \gamma_r (2|m|)!}{4 \pi (2|m|(|m|!)^2}. \quad (3.13)$$

Thus when $|\Omega| > \gamma_r$, we have

$$\inf_{\phi \in S} E_{\beta,\Omega}(\phi) \leq \begin{cases} \lim_{m \to \infty} E_{\beta,\Omega}(\phi_m) & \Omega > 0, \\ \lim_{m \to \infty} E_{\beta,\Omega}(\phi_{-m}) & \Omega < 0 \end{cases}$$

$$= \lim_{m \to \infty} (|m| + 1) \gamma_r - |\Omega| |m| + \gamma_r + \frac{\beta_2 \gamma_r (2|m|)!}{4 \pi (2|m|(|m|!)^2}, \quad (3.14)$$

This implies that there is no minimizer of the minimization problem (3.1) when $|\Omega| > \gamma_{xy}$ in 2D.

Similarly, in 3D, let

$$\phi_m(x) = \phi_m(r, \theta, z) = \phi_m(r, z) e^{im\theta}, \quad \text{with} \quad \phi_m(r, z) = \frac{\gamma_r (|m| + 1)^{1/4} e^{\frac{r|m|}{\gamma_r}}}{\sqrt{2 \pi} (|m|!)^{3/4}},$$

$$\frac{\gamma_r}{\sqrt{2 \pi} (|m|!)^{3/4}} e^{-\frac{r^2 + \frac{\gamma_r \gamma_r z^2}{2}}{2}}, \quad (3.15)$$

where $m$ is an integer. In fact, $\phi_m(x)$ is the central vortex line state with winding number $m$ of the GPE (2.8) with $d = 3$, $\beta_d = 0$ and $\Omega = 0$. It is easy to check that

$$\|\phi_m\| = 2\pi \int_0^\infty \int_0^\infty |\phi_m(r, z)|^2 r \, dr \, dz = 1, \quad m \in \mathbb{Z},$$

$$\left| \frac{1}{2} \left[ -\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial}{\partial r} \right) - \frac{\partial^2}{\partial z^2} + r^2 + \frac{m^2}{r^2} + \gamma_r^2 z^2 \right] \phi_m(r, z) \right| = (|m| + 1) \gamma_r + \frac{\gamma_r^2}{2} \phi_m.$$

Therefore $\phi_m(x) \in S$ and

$$E_{\beta,\Omega}(\phi_m(x)) \leq (|m| + 1) \gamma_r + \frac{\gamma_r^2}{2} - \Omega m + \beta_3 \pi \int_0^\infty \int_0^\infty |\phi_m(r, z)|^4 r \, dr \, dz$$

$$= (|m| + 1) \gamma_r + \frac{\gamma_r^2}{2} - \Omega m + \frac{\beta_3 \gamma_r (2|m|)!}{2 (2\pi)^{3/2} (2|m|(|m|!)^2}. \quad (3.16)$$
Thus for $|\Omega| > \gamma_r$ in 3D, we have
\[
\inf_{\phi \in S} E_{\beta, \Omega}(\phi) \leq \begin{cases} 
\lim_{m \to -\infty} E_{\beta, \Omega}(\phi_m) & \Omega > 0 \\
\lim_{m \to -\infty} E_{\beta, \Omega}(\phi_{-m}) & \Omega < 0
\end{cases}
\]
\[
= \lim_{m \to -\infty} (\gamma - r - |\Omega|)|m| + \gamma_r + \frac{\gamma_z}{2} + \frac{\beta_3 \gamma_r \gamma_z^{1/2}(2|m|)!}{2(2\pi)^{3/2}(2|m|(|m|))^{2}}
\]
\[
= -\infty. \tag{3.17}
\]
Again this implies that there is no minimizer of the minimization problem (3.1) when $|\Omega| > \gamma_r$ in 3D.

Remark 3.1 When $\gamma_{xy} < |\Omega| < \gamma_r$ in an anisotropic trap, although no rigorous mathematical justification, our numerical results in Section 6 show that there is no ground state of the energy functional $E_{\beta, \Omega}(\phi)$.

3.3 Stationary states as minimizer/saddle points in the linear case

For the stationary states of (2.12), we have the following lemma, valid in the linear case $\beta_d = 0$:

Lemma 3.2 Suppose $\beta_d = 0$, $|\Omega| < \gamma_{xy}$ and $V_d(x) \geq 0$ for $x \in \mathbb{R}^d$, we have

(i). The ground state $\phi_g$ is a global minimizer of $E_{0, \Omega}(\phi)$ over $S$.

(ii). Any excited state $\phi_j$ is a saddle point of $E_{0, \Omega}(\phi)$ over $S$.

Proof: Let $\phi_e$ be an eigenfunction of the eigenvalue problem (2.12) and (2.13). The corresponding eigenvalue is $\mu_e$. For any function $\phi$ such that $E_{0, \Omega}(\phi) \leq \infty$ and $\|\phi_e + \phi\| = 1$, notice (2.13), we have that
\[
\|\phi\|^2 = \|\phi + \phi_e\|^2 - \|\phi_e\|^2 - \int_{\mathbb{R}^d} (\phi^* \phi_e + \phi \phi_e^*) \, dx
\]
\[
= -\int_{\mathbb{R}^d} (\phi^* \phi_e + \phi \phi_e^*) \, dx. \tag{3.18}
\]
From (2.10) with $\psi = \phi_e + \phi$, notice (2.13) and (3.18), integration by parts, we get
\[
E_{0, \Omega}(\phi_e + \phi) = \int_{\mathbb{R}^d} \left[ \frac{1}{2} \nabla \phi_e^2 + V_d(x)|\phi_e|^2 - \Omega_e \phi_e \right] \, dx + \int_{\mathbb{R}^d} \left[ \frac{1}{2} \nabla \phi^2 + V_d(x)|\phi|^2 - \Omega \phi \right] \, dx
\]
\[
+ \int_{\mathbb{R}^d} \left( -\frac{1}{2} \Delta \phi_e + V_d(x)\phi_e - \Omega \phi_e \right) \phi + \left( -\frac{1}{2} \Delta \phi + V_d(x)\phi - \Omega \phi \right) \phi^* \right] \, dx
\]
\[
= E_{0, \Omega}(\phi_e) + E_{0, \Omega}(\phi) - \mu_e \|\phi\|^2 = E_{0, \Omega}(\phi_e) + [E_{0, \Omega}(\phi/\|\phi\|) - \mu_e] \|\phi\|^2. \tag{3.19}
\]
(i) Taking $\phi_e = \phi_g$ and $\mu_e = \mu_g$ in (3.19) and noticing $E_{0, \Omega}(\phi/\|\phi\|) \geq E_{0, \Omega}(\phi_g) = \mu_g$ for any $\phi \neq 0$, we get immediately that $\phi_g$ is a global minimizer of $E_{0, \Omega}$ over $S$.

(ii) Taking $\phi_e = \phi_j$ and $\mu_e = \mu_j$ in (3.19), since $E_{0, \Omega}(\phi_g) < E_{0, \Omega}(\phi_j)$ and it is easy to find an eigenfunction $\phi$ of (2.12) such that $E_{0, \Omega}(\phi) > E_{0, \Omega}(\phi_j)$, we get immediately that $\phi_j$ is a saddle point of the functional $E_{0, \Omega}(\phi)$ over $S$. \qed
3.4 Approximate ground state

When $\beta_d = 0$ and $\Omega = 0$, the ground state solution is given explicitly [8]

$$
\phi_{0,0}^g(x) = \frac{1}{\pi^{d/4}} \left\{ \begin{array}{ll}
(\gamma_x\gamma_y)^{1/4}e^{-(\gamma_x x^2 + \gamma_y y^2)/2}, & d = 2, \\
(\gamma_x\gamma_y\gamma_z)^{1/4}e^{-(\gamma_x x^2 + \gamma_y y^2 + \gamma_z z^2)/2}, & d = 3.
\end{array} \right.
$$

(3.20)

In fact, this solution can be viewed as an approximation of the ground state for a weakly interacting slowly rotating condensate, i.e. $|\beta_d| \ll 1$ and $|\Omega| \approx 0$.

For a condensate with strong repulsive interaction, i.e. $\beta_d \gg 1$, $|\Omega| \approx 0$, $\gamma_x = O(1)$, $\gamma_y = O(1)$ and $\gamma_z = O(1)$, the ground state can be approximated by the TF approximation in this regime [1, 7, 8, 9]:

$$
\phi_{\beta}^{TF}(x) = \left\{ \begin{array}{ll}
\sqrt{(\mu_{\beta}^{TF} - V_d(x))/\beta_d}, & \text{if } V_d(x) < \mu_{\beta}^{TF}, \\
0, & \text{otherwise},
\end{array} \right.
$$

(3.21)

Clearly $\phi_{\beta}^{TF}$ is not differentiable at $V_d(x) = \mu_{\beta}^{TF}$, thus $E_{\beta,\Omega}(\phi_{\beta}^{TF}) = \infty$ and $\mu_{\beta,\Omega}(\phi_{\beta}^{TF}) = \infty$ [7, 9]. This shows that one cannot use (2.10) to define the energy of the TF approximation (3.21). How to define the energy of the TF approximation is not clear in the literature. Using (2.14), (3.22) and (3.21), here we present a way to define the energy of the TF approximation (3.21) [9]:

$$
E_{\beta,\Omega}^{TF} = \mu_{\beta,\Omega}^{TF} - \int_{\mathbb{R}^d} \frac{\beta_d}{2} |\phi_{\beta}^{TF}(x)|^4 \, dx = \frac{d + 2}{d + 4} \mu_{\beta}^{TF}, \quad d = 2, 3.
$$

(3.23)

Our numerical results in Section 6 show that the TF approximation (3.21) is very accurate for the density of the ground state when $\beta_d \ll 1$ and $|\Omega| < \gamma_{xy}$, and (3.22) and (3.23) converge to the chemical potential and energy respectively only when $|\Omega| \approx 0$, but diverge when $|\Omega|$ is near $\gamma_{xy}$.

4 Excited states

In this section, we present symmetric, central vortex states and their energies of rotating BEC in 2D with radial symmetry and 3D with cylindrical symmetry, i.e. $\gamma_x = \gamma_y = 1$ in (2.8). These states, as well as their stability and interaction, were widely studied in non-rotating BEC [7, 12, 13, 27, 28, 6, 9, 5]. They are also very interesting in rotating BEC [11, 20, 34, 38, 23, 26]. In fact, they will be used as initial data for studying quantized vortex stability [33, 24, 21], dynamics [35, 44] and interaction in superfluidity [42].

4.1 Central vortex ground state

One interesting excited state is a vortex state whose energy minimizes the energy functional among all $\phi \in S$ which is locally a central vortex near the origin in 2D
and a central vortex line near the z-axis in 3D. To be specific, in 2D, let

\[ S_v = \{ \phi(x) \in \mathbb{C} \mid \| \phi \| = 1, E_{\beta, \Omega}(\phi) < \infty, \phi(0,0) = 0, (0,0) \text{ is a vortex center of } \phi \} \]

and in 3D

\[ S_v = \{ \phi(x) \in \mathbb{C} \mid \| \phi \| = 1, E_{\beta, \Omega}(\phi) < \infty, \phi(0,0,z) = 0, (0,0,z) (z \in \mathbb{R}) \text{ is a vortex line of } \phi \}. \]

Clearly \( S_v \) is a subset of the unit sphere \( S \), i.e. \( S_v \subset S \). Then the central vortex ground state \( \phi^v(x) := \phi_{\beta, \Omega}^v(x) \) is found by minimizing the energy functional \( E_{\beta, \Omega}(\phi) \) over the set \( S_v \subset S \):

(I) Find \( (\mu_{\beta, \Omega}^v, \phi_{\beta, \Omega}^v) \in S_v \) such that

\[ E^v := E_{\beta, \Omega}^v = E_{\beta, \Omega}(\phi_{\beta, \Omega}^v) = \min_{\phi \in S_v} E_{\beta, \Omega}(\phi), \quad \mu^v := \mu_{\beta, \Omega}^v = \mu_{\beta, \Omega}(\phi_{\beta, \Omega}^v). \]  

Similarly as the proof for ground state, we have the following theorem for central vortex ground state:

**Theorem 4.1**

i) In 2D, if \( \phi_{\beta, \Omega}(x,y) \in S_v \) is a central vortex ground state of the energy functional \( E_{\beta, \Omega}(\phi) \), then \( \phi_{\beta, \Omega}(x,-y) \in S_v \) and \( \phi_{\beta, \Omega}(-x,y) \in S_v \) are central vortex ground states of the energy functional \( E_{-\beta, -\Omega}(\phi) \). Furthermore

\[ E_{\beta, \Omega}^v = E_{-\beta, -\Omega}^v, \quad \mu_{\beta, \Omega}^v = \mu_{-\beta, -\Omega}^v. \]  

ii) In 3D, if \( \phi_{\beta, \Omega}(x,y,z) \in S_v \) is a central vortex ground state of the energy functional \( E_{\beta, \Omega}(\phi) \), then \( \phi_{\beta, \Omega}(x,-y,z) \in S_v \) and \( \phi_{\beta, \Omega}(-x,y,z) \in S_v \) are central vortex ground states of the energy functional \( E_{-\beta, -\Omega}(\phi) \), and (4.2) is also valid.

iii). When \( \beta_d \geq 0 \) and \( |\Omega| < \gamma_{xy} \), there exists a minimizer for the minimization problem (4.1), i.e. there exists central vortex ground state.

iv). When \( \beta_d \geq 0 \) and \( |\Omega| > \gamma_{xy} \), there exists no central vortex ground state.

The CNGF and BEFD discretization for computing ground state in section 5 can also be applied to compute central vortex ground state numerically for \( \beta_d \geq 0 \) and \( |\Omega| < \gamma_{xy} \) provided that we choose appropriate initial data for them.

### 4.2 Symmetric and central vortex states

In 2D with radially symmetric trap, i.e. \( d = 2 \) and \( \gamma_y = \gamma_x := \gamma_r \) in (2.8), we consider wave function of the form

\[ \psi(x,t) = e^{-i \mu_m t} \phi_m(x,y) = e^{-i \mu_m t} \phi_m(r)e^{im\theta}, \]  

where \( m \) is an integer which corresponds to a symmetric state when \( m = 0 \) with \( \phi_0(0) = 0 \) and to central vortex states when \( m \neq 0 \) (\( m \) is usually called index or winding number in this case) with \( \phi_m(0) = 0 \), \( \mu_m \) is the chemical potential, and
\( \phi_m(r) \) is a real function independent of time \( t \) and angle \( \theta = \text{Arg}(x) \). Inserting (4.3) into (2.8) gives the following equation for \( \phi_m(r) \) with \( 0 < r < \infty \)

\[
\mu_m \phi_m(r) = \frac{1}{2} \left[ -\frac{1}{r} \frac{d}{dr} \left( r \frac{d}{dr} \right) \phi_m + \gamma r^2 r^2 + \frac{\gamma}{r^2} + 2\beta_2|\phi_m|^2 - 2m\Omega \right] \phi_m, \tag{4.4}
\]

\[
\phi_m'(0) = 0 \quad (m = 0), \quad \text{and resp.} \quad \phi_m(0) = 0 \quad (m \neq 0), \tag{4.5}
\]

\[
\lim_{r \to \infty} \phi_m(r) = 0. \tag{4.6}
\]

under the normalization condition

\[
2\pi \int_0^\infty |\phi_m(r)|^2 r \, dr = 1. \tag{4.7}
\]

In order to find the radially symmetric state \((m = 0)\), and resp., central vortex states with index \( m \) \((m \neq 0)\), \( \phi_{\beta,\Omega}^m(x, y, z) = \phi_{\beta,\Omega}^m(r)e^{im\theta} \), we need to find a real nonnegative function \( \phi^m(r) := \phi_{\beta,\Omega}^m(r) \) which minimizes the energy functional

\[
E_{\beta,\Omega}^m(\phi(r)) = E_{\beta,\Omega}(\phi(r)e^{im\theta})
\]

\[
= \pi \int_0^\infty \left[ |\phi(r)|^2 + \left( \frac{\gamma}{r^2} + \frac{m^2}{r^2} \right) |\phi(r)|^2 + \beta_2|\phi(r)|^4 - 2m\Omega|\phi(r)|^2 \right] r \, dr
\]

\[
= E_{\beta,0}^m(\phi(r)) - m\Omega, \quad \Omega \in \mathbb{R}, \tag{4.8}
\]

over the set \( S_0 = \{ \phi(r) \in \mathbb{R} \mid 2\pi \int_0^\infty |\phi(r)|^2 r \, dr = 1, \ E_{\beta,0}^m(\phi) < \infty, \ \phi'(0) = 0 \ (m = 0), \ \text{and resp.} \ \phi(0) = 0 \ (m \neq 0) \} \). The existence and uniqueness of nonnegative minimizer for this minimization problem can be obtained similarly as for the ground state when \( \Omega = 0 \) [31]. Note that the set \( S_m = \{ \phi(r)e^{im\theta} \mid \phi \in S_0 \} \subset S \) is a subset of the unit sphere, so \( \phi_{\beta,\Omega}^m(r)e^{im\theta} \) is a minimizer of the energy functional \( E_{\beta,\Omega}(\phi) \) over the set \( S_m \subset S \). When \( \beta_2 = 0 \) and \( \Omega = 0 \) in (2.8), \( \phi_{\beta,0}^m(r) = \frac{1}{\sqrt{\pi|m|!}} r^{|m|} e^{-\gamma r^2/2} \) [6].

Similarly, in order to find the cylindrically symmetric state \((m = 0)\), and resp. central vortex line states \((m \neq 0)\), in 3D with cylindrical symmetry, i.e. \( d = 3 \) and \( \gamma_y = \gamma_x := \gamma_r \) in (2.8), we write

\[
\psi(x, t) = e^{-imt} \phi_m(x, y, z) = e^{-imt} \phi_m(r, z)e^{im\theta}, \tag{4.9}
\]

where \( m \) is an integer and called as index when \( m \neq 0 \), \( \mu_m \) is the chemical potential, and \( \phi_m(r, z) \) is a real function independent of time and angle. Inserting (4.9) into (2.8) with \( d = 3 \) gives the following equation for \( \phi_m(r, z) \)

\[
\mu_m \phi_m = \frac{1}{2} \left[ -\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial}{\partial r} \right) \phi_m + \frac{\partial^2}{\partial z^2} + \gamma_r^2 r^2 + \frac{m^2}{r^2} + 2\beta_3|\phi_m|^2 - 2m\Omega \right] \phi_m, \tag{4.10}
\]

\[
\frac{\partial}{\partial z} \phi_m(0, z) = 0 \quad (m = 0), \quad \text{and resp.} \quad \phi_m(0, z) = 0 \quad (m \neq 0), \quad z \in \mathbb{R}, \tag{4.11}
\]

\[
\lim_{r \to \infty} \phi_m(r, z) = 0, \quad -\infty < z < \infty, \quad \lim_{|z| \to \infty} \phi_m(r, z) = 0, \quad 0 \leq r < \infty. \tag{4.12}
\]
under the normalization condition
\[
2\pi \int_{0}^{\infty} \int_{-\infty}^{\infty} |\phi_m(r,z)|^2 \, r \, drdz = 1. \tag{4.13}
\]

In order to find the cylindrically symmetric state \((m = 0)\), and resp. central vortex line states \((m \neq 0)\) \(\phi^m_{\beta,\Omega}(x, y, z) = \phi^m_{\beta,\Omega}(r, z)e^{im\theta}\), we compute a real nonnegative function \(\phi^m(r, z) := \phi^m_{\beta,\Omega}(r, z)\) which minimizes the energy functional

\[
E^m_{\beta,\Omega}(\phi(r, z)) = E_{\beta,\Omega}(\phi(r, z))
\]

\[
= \pi \int_{0}^{\infty} \int_{-\infty}^{\infty} \left[ \partial_r \phi^2 + |\partial_z \phi|^2 + \left( \gamma_r^2 r^2 + \gamma_z^2 z^2 + \frac{m^2}{r^2} - 2m\Omega \right) |\phi|^2 + \beta_\Omega |\phi|^4 \right] r \, drdz
\]

\[
= E^m_{\beta,0}(\phi(r, z)) - m\Omega, \quad \Omega \in \mathbb{R},
\tag{4.14}
\]

over the set \(S_0 = \{ \phi(r, z) \in \mathbb{R} \mid 2\pi \int_{0}^{\infty} \int_{-\infty}^{\infty} |\phi(r, z)|^2 r \, drdz = 1, E^m_{\beta,0}(\phi) < \infty, \partial_r \phi(0, r) = 0 \ (m = 0)\), and resp. \(\phi(0, z) = 0 \ (m \neq 0)\), \(-\infty < z < \infty\}.\)

The existence and uniqueness of a nonnegative minimizer for this minimization problem can be obtained similarly as for the ground state when \(\Omega = 0\) \([31]\). Note that the set \(S_m = \{ \phi(r, z)e^{im\theta} \mid \phi \in S_0 \} \subset S\) is a subset of the unit sphere, so \(\phi^m_{\beta,\Omega}(r, z)e^{im\theta}\) is a minimizer of the energy functional \(E_{\beta,\Omega}(\phi)\) over the set \(S_m \subset S\). When \(\beta_\Omega = 0\) and \(\Omega = 0\) in (2.8), \(\phi^m_{0,0}(r, z) = \frac{2^{(|m|+1)/2} \sqrt{\pi} }{|m|!} r^{|m|/2} e^{-(\gamma r^2 + \gamma z^2)/2} [6]\).

When \(\beta_d > 0\), the CNGF and its BEFD discretization proposed in [6] for \(\Omega = 0\) can be applied directly to compute the central vortex states for \(\Omega \neq 0\).

From the above discussions, for symmetric states and central vortex states in rotating BEC, we have

**Lemma 4.1**

i) The radially (in 2D) and cylindrically (in 3D) symmetric states, and central vortex states are independent of the angular momentum term, i.e.

\[
\phi^m_{\beta,\Omega} = \phi^m_{\beta,0}, \quad \beta_d \geq 0, \quad \Omega \in \mathbb{R}, \quad m \in \mathbb{Z}.
\]

ii) The energy and chemical potential are independent of \(\Omega\) for the symmetric states, and resp. are changing linearly with respect to \(\Omega\) for the central vortex states, i.e.

\[
E^m : = E^m_{\beta,\Omega}(\phi^m_{\beta,\Omega}) = E^m_{\beta,0}(\phi^m_{\beta,0}) - m\Omega,
\]

\[
\mu^m : = \mu^m_{\beta,\Omega}(\phi^m_{\beta,\Omega}) = \mu^m_{\beta,0}(\phi^m_{\beta,0}) - m\Omega, \quad \beta_d \geq 0, \quad \Omega \in \mathbb{R}, \quad m \in \mathbb{Z}.
\]

iii) When \(\Omega = 0 \& \beta_d \geq 0\), the symmetric state is the same as the ground state, i.e. \(\phi^0_{\beta,\Omega} = \phi^0_{\beta,\Omega}\), and the central vortex state with index \(m = 1\) is the same as the central vortex ground state, i.e. \(\phi^1_{0,\Omega} = \phi^1_{\beta,\Omega}\).
4.3 Critical angular velocity in symmetric trap

In 2D with radial symmetry and in 3D with cylindrical symmetry, for any \( \beta_d \geq 0 \), when \( \Omega = 0 \), the ground state satisfies \( \phi_{\beta,0}^\beta(x) = \phi_{\beta,0}^0(r) \) in 2D and \( \phi_{\beta,0}^\beta(x) = \phi_{\beta,0}^0(r,z) \) in 3D, i.e. the ground state is symmetric. When \( \Omega \) increases to a critical angular velocity, \( \Omega^c_\beta \), defined as

\[
\Omega^c_\beta := \max \left\{ \Omega \mid E_{\beta,\Omega}(\phi_{\beta,0}^\beta) = E_{\beta,\Omega}(\phi_{\beta,0}^0) \right\},
\]

the energy of the ground state will be less than that of the symmetric state, i.e. symmetry breaking occurs in the ground state [40, 41]. \( \Omega^c_\beta \) is also called as critical angular velocity for symmetry breaking in the ground state.

Similarly, for any \( \beta_d \geq 0 \), when \( \Omega = 0 \), the central vortex ground state satisfies \( \phi_{\beta,0}^v(x) = \phi_{\beta,0}^1(r)e^{i\theta} \) in 2D and \( \phi_{\beta,0}^v(x) = \phi_{\beta,0}^1(r,z)e^{i\theta} \) in 3D. When \( \Omega \) increases to a critical angular velocity, \( \Omega^v_\beta \), defined as

\[
\Omega^v_\beta := \max \left\{ \Omega \mid E_{\beta,\Omega}(\phi_{\beta,0}^v) = E_{\beta,\Omega}(\phi_{\beta,0}^1) - \Omega \right\},
\]

the energy of \( \phi_{\beta,\Omega}^v \) will be less than that of the index 1 central vortex state. We call \( \Omega^v_\beta \) as critical angular velocity for symmetry breaking in the central vortex ground state.

From the above discussions and our numerical computations presented later, we find

\[
\Omega^c_0 = \Omega^v_0 = \gamma_r, \quad 0 \leq \Omega^c_\beta < \Omega^v_\beta \leq \gamma_r, \quad \text{for} \quad \beta_d > 0.
\]

5 Normalized gradient flow and its discretization

In this section, we extend the CNGF and its BEFD discretization, proposed in [6] for computing ground states of non-rotating BEC, to compute ground state and central vortex ground states of rotating BEC, i.e. minimizers of (3.1) and (4.1).

5.1 Gradient flow with discrete normalization(GFDN)

Various algorithms, e.g. imaginary time method [15, 1, 2], Sobolev gradient method [25, 24], finite element approximation [8, 46], iterative method [14] etc., for finding the minimizer of the minimization problem (3.1) have been studied in the literatures. Perhaps one of the more popular technique for dealing with the normalization constraint (2.13) is through the splitting (or projection) scheme: (i). Apply the steepest decent method to an unconstrained minimization problem; (ii) project the solution back to the unit sphere \( S \). This suggests us to consider

\[
\phi_t = -\frac{\delta E_{\beta,\Omega}(\phi)}{\delta \phi} = \frac{1}{2} \Delta \phi - V_d(x)\phi - \beta_d |\phi|^2 \phi + \Omega L_d \phi, \quad t_n < t < t_{n+1},
\]

(5.1)

\[
\phi(x, t_{n+1}) \Delta \phi(x, t_{n+1}) = \frac{\phi(x, t_{n+1})}{||\phi(x, t_{n+1})||}, \quad x \in \mathbb{R}^d, \quad n \geq 0,
\]

(5.2)

\[
\phi(x, 0) = \phi_0(x), \quad x \in \mathbb{R}^d \quad \text{with} \quad ||\phi_0|| = 1;
\]

(5.3)
where \( 0 = t_0 < t_1 < t_2 < \cdots < t_n < \cdots \) with \( \Delta t_n = t_{n+1} - t_n > 0 \) and \( k = \max_{n \geq 0} \Delta t_n \), and \( \phi(x, t_n^+) = \lim_{t \to t_n^-} \phi(x, t) \). In fact, the gradient flow (5.1) can be viewed as applying the steepest descent method to the energy functional \( E_{\beta, \Omega}(\phi) \) without constraint and (5.2) then projects the solution back to the unit sphere in order to satisfy the constraint (2.13). From the numerical point of view, the gradient flow (5.1) can be solved via traditional techniques and the normalization of the gradient flow is simply achieved by a projection at the end of each time step.

### 5.2 Energy diminishing

Let

\[
\tilde{\phi}(\cdot, t) = \frac{\phi(\cdot, t)}{\|\phi(\cdot, t)\|}, \quad t_n \leq t \leq t_{n+1}, \quad n \geq 0. \tag{5.4}
\]

For the gradient flow (5.1), it is easy to establish the following basic facts:

**Lemma 5.1** Suppose \( V_d(x) \geq 0 \) for all \( x \in \mathbb{R}^d \), \( \beta_d \geq 0 \) and \( \|\phi_0\| = 1 \), then

(i). \( \|\phi(\cdot, t)\| \leq \|\phi(\cdot, t_n)\| = 1 \) for \( t_n \leq t < t_{n+1}, \quad n \geq 0 \).

(ii). For any \( \beta_d \geq 0 \), and all \( t' \), \( t \) with \( t_n \leq t' < t < t_{n+1} \):

\[
E_{\beta, \Omega}(\phi(\cdot, t)) \leq E_{\beta, \Omega}(\phi(\cdot, t')), \quad n \geq 0. \tag{5.5}
\]

(iii). For \( \beta_d = 0 \),

\[
E_{0, \Omega}(\phi(\cdot, t)) \leq E_{0, \Omega}(\tilde{\phi}(\cdot, t_n)), \quad t_n \leq t \leq t_{n+1}, \quad n \geq 0. \tag{5.6}
\]

**Proof:** (i) and (ii) follows the standard techniques used for gradient flows. As for (iii), from (2.10) with \( \psi = \tilde{\phi} \) and \( \beta_d = 0 \), (5.1), (5.3) and (5.4), integration by parts and the Schwartz inequality, we obtain

\[
\frac{d}{dt} E_{0, \Omega}(\tilde{\phi}) = \frac{d}{dt} \int_{\mathbb{R}^d} \left[ \frac{1}{2} \frac{\|\phi\|^2}{\|\phi\|^2} + \frac{V_d(x)\|\phi\|^2}{\|\phi\|^2} - \frac{\Omega^* L_z \phi}{\|\phi\|^2} \right] dx
\]

\[
= \int_{\mathbb{R}^d} \left[ \frac{\Delta \phi^* + \nabla \phi^* \cdot \nabla \phi}{2\|\phi\|^2} + \frac{V_d(x)\|\phi\|^2}{\|\phi\|^2} - \frac{\Omega^* L_z \phi}{\|\phi\|^2} \right] dx
\]

\[
= -2 \frac{\|\phi_t\|^2}{\|\phi\|^2} + \frac{1}{2} \left( \frac{d}{dt} \frac{\|\phi\|^2}{\|\phi\|^2} \right)^2
\]

\[
\leq 0, \quad t_n \leq t \leq t_{n+1}. \tag{5.7}
\]
This implies (5.6).

From Lemma 5.1, we get immediately

\hspace{1cm}

**Theorem 5.1** Suppose \( V_d(x) \geq 0 \) for all \( x \in \mathbb{R}^d \) and \( \| \phi_0 \| = 1 \). For \( \beta_d = 0 \), GFDN (5.1)-(5.3) is energy diminishing for any time step \( k \) and initial data \( \phi_0 \), i.e.

\[ E_{0,\Omega}(\phi(\cdot, t_{n+1})) \leq E_{0,\Omega}(\phi(\cdot, t_n)) \leq \cdots \leq E_{0,\Omega}(\phi(\cdot, 0)) = E_{0,\Omega}(\phi_0), \ n \geq 0. \]  

(5.8)

### 5.3 Continuous normalized gradient flow (CNGF)

In fact, the normalized step (5.2) is equivalent to solve the following ODE exactly

\[ \phi_t(x, t) = \mu_{\phi}(t, k) \phi(x, t), \quad x \in \mathbb{R}^d, \quad t_n < t < t_{n+1}, \ n \geq 0, \]  

(5.9)

\[ \phi(x, t_n^+) = \phi(x, t_n^-), \quad x \in \mathbb{R}^d; \]  

(5.10)

where

\[ \mu_{\phi}(t, k) \equiv \mu_{\phi}(t_{n+1}, \Delta t_n) = -\frac{1}{2} \Delta t_n \ln \| \phi(\cdot, t_{n+1}) \|^2, \quad t_n \leq t \leq t_{n+1}. \]  

(5.11)

Thus the GFDN (5.1)-(5.3) can be viewed as a first-order splitting method for the gradient flow with discontinuous coefficients:

\[ \phi_t = \frac{1}{2} \Delta \phi - V_d(x) \phi - \beta \| \phi \|^2 \phi + \Omega L_z \phi + \mu_{\phi}(t, k) \phi, \quad x \in \mathbb{R}^d, \quad t \geq 0, \]  

(5.12)

\[ \phi(x, 0) = \phi_0(x), \quad x \in \mathbb{R}^d \quad \text{with} \quad \| \phi_0 \| = 1. \]  

(5.13)

Letting \( k \to 0 \) and noticing that \( \phi(x, t_{n+1}) \) on the right hand side of (5.10) is the solution of (5.1) at \( t_{n+1} = t + \Delta t_n \), we obtain

\[
\mu_{\phi}(t) := \lim_{k \to 0^+} \mu_{\phi}(t, k) = \lim_{\Delta t_n \to 0^+} \frac{1}{-2 \Delta t_n} \ln \| \phi(\cdot, t_{n+1}) \|^2 \\
= \lim_{\Delta t_n \to 0^+} \frac{1}{-2 \Delta t_n} \ln \| \phi(\cdot, (t + \Delta t_n)^-) \|^2 = \lim_{\Delta t_n \to 0^+} \frac{\frac{d}{dt} \| \phi(\cdot, t + \tau) \|^2 |_{\tau = \Delta t_n}}{-2 \| \phi(\cdot, t + \Delta t_n) \|^2} \\
= \lim_{\Delta t_n \to 0^+} \frac{\mu_{\phi, \Omega}(\phi(\cdot, t + \Delta t_n))}{\| \phi(\cdot, t + \Delta t_n) \|^2} = \frac{\mu_{\phi, \Omega}(\phi(\cdot, t))}{\| \phi(\cdot, t) \|^2}.
\]  

(5.14)

This suggests us to consider the following CNGF:

\[ \phi_t = \frac{1}{2} \Delta \phi - V_d(x) \phi - \beta_d \| \phi \|^2 \phi + \Omega L_z \phi + \mu_{\phi}(t) \phi, \quad x \in \mathbb{R}^d, \quad t \geq 0, \]  

(5.15)

\[ \phi(x, 0) = \phi_0(x), \quad x \in \mathbb{R}^d \quad \text{with} \quad \| \phi_0 \| = 1. \]  

(5.16)

In fact, the right hand side of (5.15) is the same as (2.12) if we view \( \mu_{\phi}(t) \) as a Lagrange multiplier for the constraint (2.13). Furthermore for the above CNGF, as observed in [6] for non-rotating BEC, the solution of (5.15) also satisfies the following theorem:
Theorem 5.2 Suppose $V_d(x) \geq 0$ for all $x \in \mathbb{R}^d$, $\beta_d \geq 0$ and $\|\phi_0\| = 1$. Then the CNGF (5.15)-(5.16) is normalization conserving and energy diminishing, i.e.

$$
\|\phi(\cdot, t)\|^2 = \int_{\mathbb{R}^d} |\phi(x, t)|^2 \, dx = \|\phi_0\|^2 = 1, \quad t \geq 0, \\
\frac{d}{dt} E_{\Omega}(\phi) = -2 \|\phi_t(\cdot, t)\|^2 \leq 0, \quad t \geq 0,
$$

(5.17) (5.18)

which in turn implies

$$
E_{\Omega}(\phi(\cdot, t_1)) \geq E_{\Omega}(\phi(\cdot, t_2)), \quad 0 \leq t_1 \leq t_2 < \infty.
$$

Proof: Follows the line of the analogous result for non-rotating BEC in [6].

From this theorem and the inequality (3.4), we may also get as $t \to \infty$, when $|\Omega| < \gamma_x$, $\phi$ approaches to a steady state solution which is a critical point of the energy functional $E_{\Omega}(\phi)$ [43, 6]. In non-rotating BEC, i.e. $\Omega = 0$, the unique real valued nonnegative ground state solution $\phi_g(x) \geq 0$ for all $x \in \mathbb{R}^d$ [31] is obtained by choosing a positive initial datum $\phi_0(x) \geq 0$ for $x \in \mathbb{R}^d$, e.g. the ground state solution of linear Schrödinger equation with a harmonic oscillator potential [8, 6]. For rotating BEC, e.g. $|\Omega| < \gamma_x$, our numerical results in section 6 suggest that the initial data can be chosen as a linear combination of the ground state and central vortex ground state of (2.8) when $\beta_d = 0$ and $\Omega = 0$, which are given explicitly in sections 3&4.

With this kind of initial data, the ground state solution $\phi_{\beta, \Omega}^g$ and its corresponding chemical potential $\mu_{\beta, \Omega}^g$ can be obtained from the steady state solution of the CNGF (5.15)-(5.16), i.e.

$$
\phi^g(x) := \phi_{\beta, \Omega}^g(x) = \lim_{t \to \infty} \phi(x, t), \quad x \in \mathbb{R}^d, \quad \mu^g := \mu_{\beta, \Omega}^g = \mu_{\beta, \Omega}(\phi_{\beta, \Omega}^g).
$$

(5.19)

Furthermore, when $\gamma_y = \gamma_x$ in (2.8), our numerical results also suggest that when the initial data is chosen as the central vortex ground state of (2.8) when $\beta_d = 0$ and $\Omega = 0$, the steady state solution of the CNGF (5.15)-(5.16) converges to the central vortex ground state solution $\phi_{\beta, \Omega}^v$ as $t \to \infty$, i.e.

$$
\phi^v(x) := \phi_{\beta, \Omega}^v(x) = \lim_{t \to \infty} \phi(x, t), \quad x \in \mathbb{R}^d, \quad \mu^v := \mu_{\beta, \Omega}^v = \mu_{\beta, \Omega}(\phi_{\beta, \Omega}^v)
$$

(5.20)

Rigourous mathematical justification for these observations is under further study.

5.4 Fully numerical discretization

We now present a numerical method to discretize the GFDN (5.1)-(5.3) (or a full discretization of CNGF (5.15)-(5.16)). For simplicity of notation we introduce the method for the case of 2D over a rectangle $\Omega_x = [a, b] \times [c, d]$ with homogeneous Dirichlet boundary conditions. Generalizations to 3D are straightforward for tensor product grids and the results remain valid without modifications.
We choose the spatial mesh sizes $h_x = \Delta x > 0, h_y = \Delta y > 0$ with $h_x = (b - a)/M$, $h_y = (d - c)/N$ and $M, N$ even positive integers, the time step is given by $k = \Delta t > 0$ and define grid points and time steps by

$$x_j := a + j h_x, \quad j = 0, 1, \cdots, M, \quad y_l := c + l h_y, \quad l = 0, 1, \cdots, N,$$

$$t_n := n k, \quad n = 0, 1, 2, \cdots$$

Let $\phi_{n,j,l}^n$ be the numerical approximation of $\phi(x_j, y_l, t_n)$ and $\phi^n$ the solution vector at time $t = t_n = nk$ with components $\phi_{n,j,l}^n$.

We use backward Euler for time discretization and second-order centered finite difference for spatial derivatives. The detail scheme is:

$$\frac{\tilde{\phi}_{j,l} - \phi_{j,l}^n}{k} = \frac{1}{2h_x^2} [\tilde{\phi}_{j+1,l} - 2\tilde{\phi}_{j,l} + \tilde{\phi}_{j-1,l}] + \frac{1}{2h_y^2} [\tilde{\phi}_{j,l+1} - 2\tilde{\phi}_{j,l} + \tilde{\phi}_{j,l-1}]
- V_2(x_j, y_l)\tilde{\phi}_{j,l} - \beta_2 \left| \tilde{\phi}_{j,l} \right|^2 \tilde{\phi}_{j,l} + i\Omega y_l \frac{\tilde{\phi}_{j+1,l} - \tilde{\phi}_{j-1,l}}{2h_x} - i\Omega x_j \frac{\tilde{\phi}_{j,l+1} - \tilde{\phi}_{j,l-1}}{2h_y},$$

$$j = 1, \cdots, M - 1, \quad l = 1, \cdots, N - 1,$n$$

$$\tilde{\phi}_{0,l} = \tilde{\phi}_{M,l} = \tilde{\phi}_{j,0} = \tilde{\phi}_{j,N} = 0, \quad j = 0, \cdots, M, \quad l = 0, \cdots, N,$$

$$\phi_{n+1,j,l}^n = \frac{\tilde{\phi}_{j,l}^n}{\|\phi\|^2}, \quad j = 0, 1, \cdots, M, \quad l = 0, \cdots, N, \quad n = 0, 1, \cdots, (5.21)$$

$$\phi_{j,l}^0 = \phi_0(x_j, y_l), \quad j = 0, 1, \cdots, M; \quad l = 0, \cdots, N,$$

where the norm is defined as $\|\phi\|^2 = h_x h_y \sum_{j=1}^{M-1} \sum_{l=1}^{N-1} |\tilde{\phi}_{j,l}|^2$.

6 Numerical results

In this section, we will show how to choose initial data for computing ground state of rotating BEC, and present numerical results of ground state, symmetric state, central vortex states and central vortex ground state, as well as their energy diagrams in 2D and 3D. Furthermore, we also study numerically dimension reduction from 3D to 2D, errors between ground state and its TF approximation and critical angular speed. Due to lemma 3.1, theorem 3.1, we only present results for $0 \leq \Omega < \gamma_x$. In all computations, the bounded computational domain $\Omega$ is chosen as a rectangle in 2D and a box in 3D, which is centered at the origin.

6.1 Initial data for computing ground state

For computing ground state of rotating BEC, as discussed in section 5, the CNGF and its BEFD discretization guarantees energy diminishing. For $|\Omega| \ll \gamma_x$, i.e. slowly rotating BEC, the initial data can be chosen as the ground state of (2.8) with $\beta_d = 0$ and $\Omega = 0$ (3.20), which is given explicitly by (3.20). When $\Omega$ increases, the ground state may break symmetry. From our primary numerical study, when $\Omega$ is

Table 6.1: Energy of the steady state solutions of the CNGF (5.12) under the BEFD discretization with four different initial data.

near \( \gamma_x \), the above choice no longer gives the ground state. Here we present a 2D example to evolve the CNGF (5.12) with its BEFD discretization for four different initial data.

**Example 1** Different choices of initial data for CNGF in 2D, i.e. we choose \( d = 2 \), \( \gamma_x = \gamma_y = 1 \) and \( \beta_2 = 100 \) in (5.12). We compute numerically the steady state solution of (5.12) under the BEFD discretization with a bounded computational domain \( \Omega_x = [-6, 6] \times [-6, 6] \) and four different initial data:

I. \( \phi_0(x, y) = \phi_{ho}^x(x, y) = \frac{x+iy}{\sqrt{\pi}} e^{-(x^2+y^2)/2}, \ (x, y) \in \Omega_x \),

II. \( \phi_0(x, y) = \phi_{ho}(x, y) = \frac{1}{\sqrt{\pi}} e^{-(x^2+y^2)/2}, \ (x, y) \in \Omega_x \),

III. \( \phi_0(x, y) = \frac{[\phi_{ho}(x, y) + \phi_{ho}^x(x, y)]/2}{\| [\phi_{ho}(x, y) + \phi_{ho}^x(x, y)]/2 \|}, \ (x, y) \in \Omega_x \),

IV. \( \phi_0(x, y) = \frac{(1 - \Omega)\phi_{ho}(x, y) + \Omega \phi_{ho}^x(x, y)}{\| (1 - \Omega)\phi_{ho}(x, y) + \Omega \phi_{ho}^x(x, y) \| }, \ (x, y) \in \Omega_x \),

The steady state solution is obtained numerically when \( \max_{j, l} |\phi_{j,l}^{n+1} - \phi_{j,l}^n| < \epsilon = 10^{-7} \). Table 6.1 shows the energy of the steady state solutions with four different initial data for \( 0 \leq \Omega < \gamma_x = 1 \) and \( \beta_2 = 10, 100 \) and 400.
From Table 6.1 and our additional numerical experiments, we have the following observation: (i) Type IV initial data gives the ground state for all $|\Omega| < \gamma_x = 1$, (ii) Types II and III initial data only give the ground state when $|\Omega|$ is near 0, (iii) Type I initial data only gives the ground state when $|\Omega|$ is less than but very near $\gamma_x = 1$.

From this numerical study for computing ground state, when $\gamma_x = \gamma_y = 1$ and $\gamma_z = O(1)$, we suggest choosing the following initial data in (5.13) for the CNGF (5.12) with its BEFD discretization:

$$
\phi_0(x) = \frac{(1 - \Omega)\phi_{ho}(x) + \Omega\phi^o_{ho}(x)}{||(1 - \Omega)\phi_{ho}(x) + \Omega\phi^o_{ho}(x)||}, \quad x \in \mathbb{R}^d,
$$

(6.22)

where

$$
\phi_{ho}(x) = \begin{cases}
\frac{1}{\sqrt{\pi}} e^{-(x^2+y^2)/2} & d = 2, \\
\frac{1}{\pi^{d/2}} e^{-(x^2+y^2+\gamma_z z^2)/2} & d = 3.
\end{cases}
$$

Under this choice of initial data, the continuation technique is no longer required for computing the ground state. Furthermore, from our numerical study, the initial data for computing the central vortex ground state can be chosen as

$$
\phi_0(x) = \phi^o_{ho}(x), \quad x \in \mathbb{R}^d.
$$

For how to choose initial data in 3D for a prolate trap in order to obtain bending vortex, we refer to [3, 21, 32, 33, 35, 44].

### 6.2 Results in 2D

#### Example 2

Ground state, symmetric state and central vortex states, as well as their energy configurations, in 2D, i.e. we take $d = 2$ and $\gamma_x = \gamma_y = 1$ in (2.8). Figure 6.1 plots surface and contour of the ground state $\phi^0(x, y) := \phi_{\beta, 0}(x, y)$ with $\beta_2 = 100$ for different $\Omega$ and Figure 6.2 for the central vortex ground state $\phi^v(x, y) := \phi_{\beta, 0}^v(x, y)$. Figure 6.3 plots the symmetric state $\phi^0(r) := \phi_{\beta, 0}^0(r)$ and first three central vortex states $\phi^m(r) := \phi_{\beta, 0}^m(r)$ ($m = 1, 2, 3$) for different interaction rate $\beta_2$. Table 6.2 and Figure 6.4 show the energy configurations of these states for different $\beta_2$ and $\Omega$. Furthermore, Figure 6.5 shows ratios between the energy of these states, and Figure 6.6 plots the energy of the ground state when $\beta_2 \gg 1$ and $\Omega \approx \gamma_x = 1$.

From Figs. 6.1-6 and Table 6.2, we reach the following conjectures for rotating BEC under an isotropic trap in 2D, i.e. $\gamma_x = \gamma_y = 1$:

(a) For any fixed $\beta_2 > 0$, there exists a critical angular frequency $0 < \Omega^c < \gamma_x = 1$ such that: (i) when $0 \leq \Omega < \Omega^c$, the ground state $\phi_{\beta, \Omega}^0 = \phi_{\beta, 0}^0$, $E_{\beta, \Omega} = E_{\beta, 0}^0 = E_{\beta, \Omega}^0$, and $\mu_{\beta, \Omega}^0 = \mu_{\beta, 0}^0 = \mu_{\beta, 0}^0$; (ii) when $\Omega = \Omega^c$, the ground state is not unique, e.g. both $\phi_{\beta, 0}^0$ and $\phi_{\beta, 0}^1$ are ground states, i.e. $E_{\beta, \Omega^c} = E_{\beta, 0}^0 = E_{\beta, \Omega^c}^0$, and $\mu_{\beta, \Omega^c}^0 = \mu_{\beta, 0}^0 = \mu_{\beta, \Omega^c}^1$; (iii) when $\Omega^c < \Omega < \gamma_x = 1$, quantized vortices appear in the ground states, and the larger $\Omega$ is the more vortices appear in the ground state.
Figure 6.1: Surface plots of ground state density function $|\phi(x, y)|^2$ in 2D with $\gamma_x = \gamma_y = 1$ and $\beta_2 = 100$ for different $\Omega$ in Example 2.

(b) Similar patterns for the central vortex ground state are observed as in (a) for the ground state.

(c) For any fixed $\beta_2 \geq 0$, when $\Omega$ increases from 0 to $\gamma_x = 1$, the energy $E_{s, \Omega}$ and chemical potential $\mu_{s, \Omega}$ ($s = g, v, 0, 1, \cdots$) of any stationary states decrease.
Furthermore, the energy of the ground state has the following asymptotics when $\Omega$ is near $\gamma_x = 1$ (cf. Fig. 6.6b):

$$E_{\beta,\Omega}^g = E_{\beta,\pm \gamma_x}^g + O(\gamma_x + \Omega), \quad \Omega \to \pm \gamma_x^\mp.$$

(d) For any fixed $|\Omega| < \gamma_x = 1$, when $\beta_2$ increases, the energy $E_{\beta,\Omega}^s$ and chemical
Figure 6.2: Surface plots of central vortex ground state density function $|\phi^v(\gamma_x, \gamma_y)|^2$ in 2D with $\gamma_x = \gamma_y = 1$ and $\beta_2 = 100$ for different $\Omega$ in Example 2.

potential $\mu^s_{\beta,\Omega}$ ($s = g, v, 0, 1, \cdots$) of any stationary states increase too, and satisfy

$$\lim_{\beta_2 \to \infty} \frac{E^v_{\beta,\Omega}}{E^g_{\beta,\Omega}} = \lim_{\beta_2 \to \infty} \frac{\mu^v_{\beta,\Omega}}{\mu^g_{\beta,\Omega}} = 1, \quad \lim_{\beta_2 \to \infty} \frac{E^g_{\beta,\Omega}}{E^g_{\beta,\Omega}} = \text{const}, \quad \lim_{\beta_2 \to \infty} \frac{\mu^g_{\beta,\Omega}}{\mu^g_{\beta,\Omega}} = \text{const}, \quad s \geq 0, \quad (6.23)$$
Figure 6.3: Symmetric and central vortex states in 2D with \(\gamma_x = \gamma_y = 1\) for \(\beta_2 = 0, 10, 100, 1000, 10000\) (in the order of decreasing of peak) in Example 2. Symmetric state \(\phi^0(r)\): a); and central vortex states \(\phi^m(r)\): b). \(m = 1, c). \(m = 2\) and d). \(m = 3\).

\[
E_{\beta,\Omega}^s = O(\beta_2^{1/2}), \quad \mu_{\beta,\Omega}^s = O(\beta_2^{1/2}), \quad \text{when} \quad \beta_2 \to \infty, \quad s = g, v, 0, 1, \ldots . \tag{6.24}
\]

**Example 3** Ground state in 2D with nonsymmetric trap, i.e., we take \(d = 2, \gamma_x = 1\) and \(\gamma_y = 1.5\) in (2.8). Figure 6.7 plots surface of the ground state \(\phi^\beta(x, y)\) with \(\beta_2 = 100\) for different \(\Omega\).

From Fig. 6.7, the conjecture (a) for ground states in Example 2 is still valid for an anisotropic trap, i.e. \(\gamma_x \neq \gamma_y > 1\), in 2D.

### 6.3 Results in 3D

**Example 4** Ground state, symmetric state and central vortex states, as well as their energy configurations, in 3D, i.e. we take \(d = 3, \gamma_x = 1, \gamma_y = 1\) and \(\gamma_z = 1\) in (2.8). Figure 6.8 plots isosurface of the ground state \(\phi^\beta(x, y, z) := \phi_{\beta,\Omega}^g(x, y, z)\) and central vortex ground state \(\phi^\beta(x, y, z) := \phi_{\beta,\Omega}^0(x, y, z)\) for different \(\Omega\). Figure 6.9 plots symmetric state \(\phi^0(r, z = 0)\), \(\phi^0(r = 0, z)\), and the first central vortex state \(\phi^1(r, z = 0)\), \(\phi^1(r = 0, z)\) for different interaction rate \(\beta\). Figure 6.10 shows the energy configurations of these states for different \(\beta\) and \(\Omega\) in 3D.
Table 6.2: Energy of the ground state $E_{g,0}^\beta$, symmetric state $E_{0,0}^\beta$, central vortex ground state $E_{v,0}^\beta$ and the first three central vortex states $E_{j,0}^\beta (j = 1, 2, 3)$ with $\gamma_x = \gamma_y = 1$ for different $\beta_2$ and $\Omega$ in 2D in Example 2.

From Figs. 6.8-10, all the conjectures at Example 2 are still valid in 3D except that (6.24) should be modified to

$$E_{g,0}^s = O(\beta^{2/5}), \quad \mu_{g,0}^s = O(\beta^{2/5}), \quad \text{when } \beta \to \infty, \quad s = g, v, 0, 1, \ldots.$$  (6.25)

For obtaining bending vortex, e.g. S-shaped vortex and U-shaped vortex, in 3D with a prolate trap, we refer to [3, 21, 32, 33, 35, 44].

### 6.4 Critical angular velocity

**Example 5** Critical angular velocities in 2D, i.e. we take $d = 2$ and $\gamma_x = \gamma_y = 1$ in (2.8). Table 6.3 displays the critical angular velocity $\Omega^c := \Omega^c_\beta$ and $\Omega'' := \Omega''_\beta$ for different $\beta_2$.

From Table 6.3, we get: (a) $\Omega^c = \Omega'' = \gamma_r = 1.0$ when $\beta_2 = 0$ and $0 < \Omega^c < \Omega'' < \gamma_r = 1$ when $\beta_2 > 0$; (b) $\Omega^c$ and $\Omega''$ decrease when $\beta_2$ increases; (c) $\Omega^c \approx E_{g,0}^\beta - E_{0,0}^\beta$ and $\Omega'' \approx E_{v,0}^\beta - E_{0,0}^\beta$ for $\beta_2 \geq 0$. All these results agree very well with the numerical results [23, 26] and analytical estimate [40, 41] in the literature. Similar observations are still valid in 3D.
Figure 6.4: Energy diagrams for ground state, i.e. \( E^g := E^g_{\beta,0} \), symmetric state, i.e. \( E^0 := E^0_{\beta,\Omega} \), central vortex states, i.e. \( E^m := E^m_{\beta,\Omega} \), and central vortex ground state, i.e. \( E^v := E^v_{\beta,\Omega} \), in 2d with \( \gamma_x = \gamma_y = 1 \) for different \( \beta_2 \) and \( \Omega \) in Example 2.

### 6.5 Numerical verification for dimension reduction

As we know, when \( \gamma_x = O(1) \), \( \gamma_y = O(1) \) and \( \gamma_z \gg 1 \), the 3D GPE can be asymptotically reduced to a 2D GPE. Here we present a numerical verification of this procedure. In order to do so, we compute the ground state \( \phi^3_{g}(x,y,z) \) of the 3D GPE, i.e. we take \( d = 3 \), \( \gamma_x = \gamma_y = 1 \) and \( \beta = 100 \) in (2.8), numerically for different \( \gamma_z \). Then we compute

\[
\phi_3(z) = \sqrt{\int_{\mathbb{R}^2} |\phi^3_{g}(x,y,z)|^2 \, dx \, dy} \approx \phi_{ho}(z) = \frac{\gamma_z^{1/4}}{\pi^{1/4}} e^{-\gamma_z z^2/2},
\]

\[
\beta_2 = \beta \int_{-\infty}^{\infty} |\phi_3(z)|^4 \, dz \approx \beta_2^2 = \beta \sqrt{\gamma_z/2\pi}.
\]
Figure 6.5: Ratios between the energy of different states in Example 2.

Figure 6.6: Asymptotics of the energy for the ground state in Example 2. a). When $\beta_2 \gg 1$, b). When $\Omega \approx 1$.

We also find the ground state $\phi_g^{2D}(x, y)$ of the 2D GPE, i.e. we take $d = 2$, $\gamma_x = \gamma_y = 1$ and $\beta_2 = 100\sqrt{\gamma_z/2\pi}$ in (2.8), numerically for different $\gamma_z$. Table 6.4 lists the errors of $\beta_2 - \beta_2^*$, $\max |\phi_3 - \phi_{ho}|$, $\|\phi_3 - \phi_{ho}\|_{L^2}$, $\max |\phi_g^{3D} - \phi_g^{2D}\phi_{ho}|$ and $\|\phi_g^{3D} - \phi_g^{2D}\phi_{ho}\|_{L^2}$ for different $\gamma_z$.

From Table 6.4, the dimension reduction of GPE from 3D to 2D when $\gamma_z \gg 1$ is
verified numerically. Furthermore, we have the following convergence rate:

\[ \beta_2 = \beta \sqrt{\frac{\gamma_z}{2\pi}} + O \left( \frac{\ln \gamma_z}{\gamma_z^{1/4}} \right), \quad \| \phi_S - \phi_{\text{ho}} \|_{L^\infty} = O \left( \frac{\ln \gamma_z}{\gamma_z^{1/4}} \right), \]

### 6.6 Errors of the TF approximation

As we know, when $\beta_d \gg 1$, $\gamma_x = O(1)$, $\gamma_y = O(1)$, $\gamma_z = O(1)$ and $|\Omega| \approx 0$, the ground state is very well approximated by the TF approximation [1, 2, 8, 9]. Here we study numerically how effective the TF approximation is, when $|\Omega|$ is large, especially when $|\Omega|$ is near $\gamma_x$. In order to do so, we compare the ground state and its TF approximation in 2D, i.e. we take $d = 2$ and $x = y = 1$ in (2.8). Table 6.5 lists the errors $\max |\phi_{\beta, \Omega}^g|^2 - |\phi_{\beta, \Omega}^{TF}|^2$, $E_{\beta, \Omega}^g - E_{\beta, \Omega}^{TF}$, and $\mu_{\beta, \Omega}^g - \mu_{\beta, \Omega}^{TF}$ for different $\beta_2 \gg 1$ and $\Omega$.

From Table 6.5, we can see that the density of the ground state converges to the TF approximation for any $|\Omega| < \gamma_x = 1$ when $\beta_2 \to \infty$. However, when $\beta_2$ increases, the energy and chemical potential of the ground state converge to those of the TF approximation only when $|\Omega| \approx 0$, but diverge when $|\Omega|$ is near $\gamma_x = 1$. This is due to the fact that more and more vortices appear in the ground state when $|\Omega|$ is near 1 and $\beta_2 \gg 1$. A similar conclusion is also valid in 3D based on our additional numerical experiments.

32
Figure 6.9: Cylindrically symmetric (upper row) and central vortex (lower row) states in 3D with $\gamma_x = \gamma_y = \gamma_z = 1$ for $\beta_3 = 0.0, 10.0, 100.0, 1000.0, 10000.0$ (in the order of decreasing of peak) in Example 4. a). $\phi^0(r, 0)$; b). $\phi^0(0, z)$; c). $\phi^1(r, 0)$; d). $\phi^1(0, z)$.

Figure 6.10: Energy diagrams for ground state, Cylindrically symmetric state, central vortex states in 3D with $\gamma_x = \gamma_y = \gamma_z = 1.0$ in Example 4 for different $\beta$ and $\Omega$.

### 6.7 Spurious numerical ground states when $|\Omega| > \gamma_x$

As discussed in section 3, for a rotating BEC, there exists a ground state when $|\Omega| < \gamma_x$ and no ground state when $|\Omega| > \gamma_x$. But when we evolve the discretization

Table 6.6 lists the numerical energies $E^h$ with $\beta_2 = 100$ and $\gamma_x = 1$ for $\gamma_y = 1$ and $\gamma_y = 1.5$, under different rotation speeds $\Omega$ and mesh sizes $h$.

From Table 6.6, we can observe that for $\gamma_y \geq 1$: (i) When $|\Omega| < \gamma_{xy} = 1$, $E^h := \lim_{h \to 0} E^h$ which implies that $\phi_{\beta,\Omega}^h$ is a good approximation of the ground state $\phi_{\beta,\Omega}^g(x)$; (ii) when $|\Omega| > \gamma_{xy}$, $\lim_{h \to 0} E^h = -\infty$ which suggests that there is no ground state when $|\Omega| > \gamma_{xy}$ and the steady state solution $\phi_{\beta,\Omega}^h$ is a spurious numerical ground state; (iii) when $\gamma_{xy} < |\Omega| \leq \gamma_{xy}$ in an anisotropic trap, our numerical results
suggest that there is no ground state. Similar results can be obtained in 3D from our additional numerical experiments.

7 Conclusion

We have studied the ground state, symmetric state and central vortex states in rotating BEC analytically and numerically based on the Gross-Pitaevskii mean field theory. Existence or nonexistence of the ground state when the dimensionless angular velocity $|\Omega| < \gamma_{xy}$ or $|\Omega| > \gamma_{xy}$, respectively, is proven in a simple but mathematically rigorous way. We also found that the symmetric and central vortex states are independent of the angular momentum rotation. Then the ground state, symmetric state and central vortex states, as well as their energies, were computed in 2D and 3D for a rotating BEC by a CNGF and BEFD discretization. Based on our asymptotic and extensive numerical studies, we can draw the following conjectures for rotating BEC:

(i) The nonlinear eigenvalue problem (2.12) admits infinite many eigenfunctions with distinct eigenvalues. When $\beta_d \geq 0$ and $|\Omega| < \gamma_x$, if all the eigenfunctions of (2.12) are ranked according to their energies, $\phi^0$, $\phi^1$, ..., then the corresponding eigenvalues (or chemical potentials) are in the same order, i.e.

$$E_{\beta,\Omega}(\phi^0) < E_{\beta,\Omega}(\phi^1) < E_{\beta,\Omega}(\phi^2) < \ldots \implies \mu_{\beta,\Omega}(\phi^0) < \mu_{\beta,\Omega}(\phi^1) < \mu_{\beta,\Omega}(\phi^2) < \ldots$$

(ii) For any fixed $\beta_d \geq 0$, there exists a critical angular frequency $0 < \Omega^c \leq \gamma_{xy}$ such that when $\Omega > \Omega^c$ the ground state breaks symmetry, i.e. quantized vortices appear in the ground state. When $\beta_d$ increases, $\Omega^c$ increases too. Similar conclusions are valid for central vortex ground state. Furthermore, we have

$$\Omega^c \approx E_{\beta,0}^1 - E_{\beta,0}^0, \quad \Omega^c \approx E_{\beta,0}^2 - E_{\beta,0}^1.$$

Table 6.6: Energy $E^h$ in 2D with $\beta_2 = 100.$
(iii) For any fixed $|\Omega| < \gamma_{xy}$, the energy and chemical potential of any stationary state increase when $\beta_d$ increase. Furthermore, when $\beta_d \to \infty$, they have the following asymptotics:

$$E^s_{\beta_d, \Omega} = O(\beta^{2/(2+d)}) \quad \mu^s_{\beta_d, \Omega} = O(\beta^{2/(2+d)})$$

when $\beta \to \infty$, $s = g, v, 0, 1, \ldots$, and the ratios between them are constants, i.e.

$$\lim_{\beta_d \to \infty} \frac{E^v_{\beta_d, \Omega}}{E^g_{\beta_d, \Omega}} = \lim_{\beta_d \to \infty} \frac{\mu^v_{\beta_d, \Omega}}{\mu^g_{\beta_d, \Omega}} = 1, \quad \lim_{\beta_d \to \infty} \frac{E^s_{\beta_d, \Omega}}{E^g_{\beta_d, \Omega}} = \text{const}, \quad \lim_{\beta_d \to \infty} \frac{\mu^s_{\beta_d, \Omega}}{\mu^g_{\beta_d, \Omega}} = \text{const}, \quad s \geq 0.$$

(iv) For any fixed $\beta_d \geq 0$, the energy and chemical potential of any stationary state decrease when $\Omega$ increases from 0 to $\gamma_{xy}$ or decreases from 0 to $-\gamma_{xy}$. Furthermore, the energy of the ground state has the following asymptotics when $\Omega$ is near $\pm \gamma_{xy}$:

$$E^g_{\beta_d, \Omega} = E^g_{\beta_d, \pm \gamma_{xy}} + O(\gamma_{xy} \mp \Omega), \quad \Omega \to \pm \gamma_{xy}.$$

(v) In disk-shaped condensation, i.e. $\gamma_x = O(1)$, $\gamma_y = O(1)$ and $\gamma_z \gg 1$, the ground state and its energy and chemical potential in 3D with interaction $\beta$ can be well approximated by those of its 2D reduction with interaction $\beta_2 = \beta \sqrt{\gamma_z/2\pi}$.

(vi) In the semiclassical regime, the TF approximation is very accurate for the density of the ground state; where the TF approximate energy and chemical potential converge to the ground state energy and chemical potential respectively only when $|\Omega| \approx 0$, but diverge when $|\Omega|$ is near $\gamma_{xy}$.
