Abstract

The three-dimensional (3D) Gross-Pitaevskii equation with strongly anisotropic confining potential is analyzed. The formal limit as the ratio of the frequencies $\varepsilon$ tends to zero provides a denumerable system of two-dimensional Gross-Pitaevskii equations, strongly coupled through the cubic nonlinearities. To numerically solve the asymptotic approximation only a finite number of limiting equations is considered. Finally, the approximation error for a fixed number of equations is compared for different $\varepsilon$ tending to zero. On the other hand, the approximation error for an increasing number of terms in the approximation is observed.

Key words: Gross-Pitaevskii equation, spectral decomposition, Fourier expansion, time splitting-spectral techniques, approximation error

1 Description of the Problem

We analyze the 3D Gross-Pitaevskii equation (GPE), which is a nonlinear Schrödinger equation with confining potential. More precisely we focus on the case when the potential

‡Institut für Analysis und Scientific Computing, TU Wien, Wiedner Hauptstr. 8-10, 1040 Vienna, Austria; Johann Radon Institute for Computational and Applied Mathematics, Altenbergstr. 69, 4040 Linz, Austria
§Institut für Mathematik, Universität Wien, Nordbergstr. 15, 1090 Vienna, Austria.
is quadratic and strongly anisotropic. Thus, we consider the following problem:

\[ i\psi_t = -\frac{1}{2} \Delta \psi + \left( \frac{|x|^2}{2} + \frac{\varepsilon^2}{2\varepsilon^4} \right) \psi + \delta |\psi|^2 \psi, \]

\[ \psi(0, x, z) = \psi_I(x, z), \quad x \in \mathbb{R}^2, \quad z \in \mathbb{R}, \]

where the parameter \( \varepsilon \), which determines the strength of the anisotropy, tends to zero. Note that \( 1/\varepsilon^2 \) is the harmonic oscillator frequency in \( z \)-direction. Furthermore, we impose the normalization condition:

\[ \int_{\mathbb{R}^3} |\psi_I|^2 dx dz = 1, \quad (1) \]

at time \( t = 0 \), which is then maintained by the equation.

At first we perform the rescaling \( z \rightarrow \varepsilon z \). In order to keep the wavefunction normalized in \( L^2(\mathbb{R}^3) \) we have to rescale \( \psi \rightarrow \varepsilon^{-1/2} \psi \). As we want to balance the nonlinearity with the terms of order 1 we choose \( \delta = \mathcal{O}(\varepsilon) \), thus we consider weak nonlinearities. After the rescaling we obtain

\[ i\psi_t = H^\perp \psi + \frac{1}{\varepsilon^2} H \psi + |\psi|^2 \psi, \quad (2) \]

\[ \psi(t = 0, x, z) = \psi_I(x, z), \]

where \( H^\perp = -\frac{1}{2} \Delta_x + \frac{|x|^2}{2} \) and \( H = -\frac{1}{2} \partial_{zz} + \frac{\varepsilon^2}{2} \) are harmonic oscillator Hamiltonians in \( x \) and \( z \) directions, respectively.

We introduce the fast time scale \( \tau = t/\varepsilon^2 \), characteristics for oscillations in the \( z \)-direction, and make the two scale ansatz \( \psi = \psi(t, \tau, x, z) \) leading to

\[ i\psi_t + i \frac{1}{\varepsilon^2} \psi_\tau = H^\perp \psi + \frac{1}{\varepsilon^2} H \psi + |\psi|^2 \psi. \]

If we let \( \varepsilon \to 0 \), we formally obtain the equation

\[ i\Psi_\tau = H \Psi, \]

which can be solved explicitly in terms of the spectral decomposition:

\[ \Psi = \sum_{k \geq 0} \phi_k e^{-i\mu_k \tau} \omega_k(z). \]

Here \( (\omega_k(z))_{k \geq 0} \) are eigenfunctions, normalized in \( L^2(\mathbb{R}) \), of the self-adjoint, nonnegative operator \( H \) (see [SR]), defined on \( L^2(\mathbb{R}) \) with the domain

\[ X_H = \{ u \in H^1(\mathbb{R}); \quad zu \in L^2(\mathbb{R}) \}. \]

The eigenvalue problem

\[ H \omega_k = \mu_k \omega_k, \]

can be solved explicitly with

\[ \mu_k = k + \frac{1}{2}, \quad \omega_k(z) = (2^k k!)^{-1/2} \left( \frac{1}{\pi} \right)^{1/4} H_k(z), \quad k = 0, 1, \cdots \]
denoting the eigenvalues and eigenfunctions respectively. Here \( H_k(z) \) are the standard Hermite polynomials. By modulation, we let \( \phi_k \) depend on the slow variables \((t, x)\). This motivates the expansion of the solution \( \psi^\varepsilon \) of (2) with respect to the eigenstates of \( H \):

\[
\psi^\varepsilon(t, x, z) = \sum_{k \geq 0} e^{-i\mu_k t/\varepsilon^2} \phi_k^\varepsilon(t, x) \omega_k(z),
\]

where \( \phi_k^\varepsilon(t, x) = \int_\mathbb{R} \psi^\varepsilon(x, z, t) \omega_k(z) dz \) are the Fourier coefficients. Substitute the expansion (3) into (2), multiply the equation by \( \omega_k e^{i\mu_k t/\varepsilon^2} \), and integrate with respect to \( z \), we obtain:

\[
i\partial_t \phi_k^\varepsilon = H^\dagger \phi_k^\varepsilon + \sum_{l, m, n \geq 0} \gamma_{klmn} e^{-i(\mu_n + \mu_l - \mu_m - \mu_k) t/\varepsilon^2} \phi_l^\varepsilon \phi_m^\varepsilon \phi_n^\varepsilon, \quad k \geq 0,
\]

where \( \gamma_{klmn} = \int_\mathbb{R} \omega_k(z) \omega_l(z) \omega_m(z) \omega_n(z) dz \). Note that all coefficients in the sum, for which \( \mu_n + \mu_l - \mu_m - \mu_k \) is different from 0, tend to zero weakly. Thus, in the limit \( \varepsilon \) to 0 we obtain formally:

\[
i\partial_t \phi_k = H^\dagger \phi_k + \sum_{l, m, n \geq 0} \gamma_{l,m,n} \phi_l \phi_m \phi_n, \quad k \geq 0,
\]

where \( \sum_{l, m, n}^{k} \) denotes the sum over all \( l, m, n \geq 0 \) such that \( \mu_n + \mu_l - \mu_m - \mu_k = 0 \), and \( \phi_m \) denotes the (weak) limit of \( \phi_m^\varepsilon \) as \( \varepsilon \) tends to zero.

The equations (5) are a denumerable system of two-dimensional GPEs, strongly coupled through the cubic nonlinearities. We want to investigate the properties of this coupling. For every fixed \( k \), all triples of the form \((l, m, n) = (l, l, k)\) appear in \( \sum_{l, m, n}^{k} \), leading to the contribution \( \sum_l \gamma_{lkk} |\phi_l|^2 \) to the potential in the \( \phi^\varepsilon \)-equation. However, by the special form of the eigenvalues of the harmonic oscillator, also other coupling terms may occur, since the condition \( \mu_n + \mu_l - \mu_m - \mu_k = 0 \) reduces to \( n + l = m + k \). For example, in the \( \phi_0 \)-equation, the term \( \gamma_{0121} |\phi_1|^2 |\phi_2|^2 \) is not of potential type.

If not all states \( \omega_k \) appear in the spectral decomposition of the initial datum \( \psi_I \), which states will appear in the solution for positive time \( t \) ? The question can be answered in terms of the following definition.

**Definition 1.** The index set \( I \subset \{0, 1, 2, \ldots \} \) is called closed, iff \((l, m, n) \in I^3 \) and \( k = l + n - m \geq 0 \) imply \( k \in I \). The closure \( \bar{I} \) of \( I \) is the smallest closed index set containing \( I \).

Now the answer to the above question is: Define \( I = \{ k \geq 0 : \phi_k(x, t = 0) \neq 0 \} \). Then, for all \( t \geq 0 \), \( \phi_k(x, t) = 0 \) for \( k \notin \bar{I} \).

It remains to characterize the closed index sets.

**Lemma 2.** A nonempty index set \( I \) is closed iff it has the form \( I = \{ p + jq : |j| \geq 0 \} \) with either \( 0 \leq p < q \) or \( q = 0 \).

**Proof.** The ‘if’ is obvious. For the proof of ‘only if’, assume that \( I \) is closed, \( \text{card}(I) > 1 \), and that \( k_0 = p < k_1 = p + q \) are the two smallest elements of \( I \). If \( p \geq q \) would hold, then \( k_0 + k_0 - k_1 = p - q \in I \). However, \( k_0 + k_0 - k_1 < k_0 \) contradicting the assumption that \( k_0 \) is the smallest element of \( I \). This proves \( p < q \).
Now we shall prove by induction that \( I \) has the form stated in the lemma. Assume \( k_j = p + jq, 0 \leq j \leq n, \) are the \( n + 1 \) smallest elements of \( I \). Then \( p + (n + 1)q = k_n + k_1 - k_0 \in I \). If there were a \( k_{n+1} \in I \) with \( k_n < k_{n+1} < p + (n + 1)q \), then \( k_n + k_n - k_{n+1} \in I \) and \( k_{n+1} < k_n + k_n - k_{n+1} < k_n \), i.e., there were an element of \( I \) between \( k_{n-1} \) and \( k_n \), contradicting our assumption that \( k_0, \ldots, k_n \) are the \( n + 1 \) smallest elements.

Closed index sets either have one element or infinitely many. In some cases they can be easily related to symmetries of the wave function. In [BMSW] the case of \( I = \{0\} \) is considered, i.e., initially only the ground state is charged. According to the observation mentioned above in this special case the system (5) will consist of only one equation for \( \phi_0 \), the modulation of the ground state. In fact in [BMSW] \( \phi_0 \) is proven to be the approximation of the solution \( \psi \) of (2) on every bounded time interval. Moreover \( \phi_0 \) satisfies (5) with \( k = 0 \). Other examples are the sets of even and odd integers, corresponding to wave functions which are, respectively, even and odd in terms of the variable \( z \).

It is a well known fact that (2) conserves mass

\[
\int_{\mathbb{R}^3} |\psi|^2 \, dx \, dz,
\]

and energy

\[
\frac{1}{\varepsilon^2} \int_{\mathbb{R}^3} \left( |\partial_x \psi|^2 + |z \psi|^2 \right) \, dx \, dz + \int_{\mathbb{R}^3} \left( |\nabla_x \psi|^2 + |x \psi|^2 + |\psi|^4 \right) \, dx \, dz. \tag{6}
\]

Mass conservation carries over to the limiting system (5) in the obvious way. If we multiply (5) by \( \overline{\phi_k} \), integrate by parts, take the imaginary part and sum over all \( k \), we obtain

\[
\frac{d}{dt} \sum_{k \geq 0} \int_{\mathbb{R}^2} |\phi_k|^2 \, dx = 0.
\]

The energy contains two terms of different orders of magnitude. We shall show that limiting versions of both terms are conserved in the limit.

First we multiply the equation (5) by \( \partial_t \overline{\phi_k} \), take the real part, integrate with respect to \( x \), and sum over all \( k \). We introduce the abbreviation

\[
\sum^* := \sum_{k \geq 0} \sum_{l,m,n}^k,
\]

i.e., the sum over all \( k, l, m, n \geq 0 \) such that \( \mu_l + \mu_m - \mu_n - \mu_k = 0 \). Taking into account the computation (exchanging \( m \) and \( k \))

\[
2 \Re \sum^* \gamma_{nmkl} \phi_l \phi_n \overline{\phi_m} \overline{\phi_k} = \Re \sum^* \gamma_{nmkl} \phi_l \phi_n (\phi_m)_t \phi_k + \phi_m (\phi_k)_t
\]

\[
= \frac{1}{2} \Re \sum^* \gamma_{nmkl} \left[ \phi_l \phi_n (\phi_m \phi_k)_t + (\phi_l \phi_n)_t \phi_m \phi_k \right]
\]

\[
= \frac{1}{2} \Re \sum^* \gamma_{nmkl} (\phi_l \phi_n \phi_m \phi_k)_t,
\]

\[
4
\]
we obtain

$$0 = \frac{d}{dt} \int_{\mathbb{R}^2} \sum_{k \geq 0} \left( |\nabla \phi_k|^2 + |x\phi_k|^2 + \Re \sum_{l,m,n} \gamma_{nmlk} \phi_l \bar{\phi}_m \phi_n \frac{t}{\epsilon} \phi_k \right) dx.$$ 

Since, by exchanging \((m, k)\) and \((l, n)\),

$$\sum^* \gamma_{nmlk} \phi_l \phi_m \phi_n \phi_k = \frac{1}{2} \sum^* \gamma_{nmlk} [\phi_l \phi_m \phi_n \phi_k + \phi_m \phi_k \phi_l \phi_n] = \sum^* \gamma_{nmlk} \Re(\phi_l \phi_m \phi_n \phi_k),$$

we deduce that \(\sum^* \gamma_{nmlk} \phi_l \phi_m \phi_n \phi_k\) is real. Therefore the quantity

$$E_1 = \int_{\mathbb{R}^2} \sum_{k \geq 0} \left( |\nabla \phi_k|^2 + |x\phi_k|^2 + \sum_{l,m,n} \gamma_{nmlk} \phi_l \phi_m \phi_n \phi_k \right) dx$$

is real and conserved by (5). It is clear that the first two terms in \(E_1\) are positive. In order to see the positivity of the exchange term in the energy we take a function \(\beta^e(t, z)\) with the expansion:

$$\beta^e(t, z) = \sum_{k \geq 0} \beta_k e^{-i\mu_k t/\epsilon^2} \omega_k(z),$$

and compute

$$0 \leq \int_{\mathbb{R}} |\beta^e(t, z)|^4 dz = \sum_{k, l, m, n \geq 0} \gamma_{nmlk} e^{-i(\mu_l - \mu_m - \mu_n - \mu_k) t/\epsilon^2} \beta_l \beta_n \bar{\beta}_m \bar{\beta}_k$$

$$\leq 0 \sum^* \gamma_{nmlk} \beta_l \beta_n \bar{\beta}_m \bar{\beta}_k.$$

This shows the nonnegativity of \(E_1\), which is a limiting version of the second \((O(1)-)\) term in the energy (6). The first term in (6) formally converges to

$$E_2 = \int_{\mathbb{R}^2} \sum_{k \geq 0} \mu_k |\phi_k|^2 dx.$$ 

For proving conservation of \(E_2\), we multiply the equation (5) by \(\mu \phi_k\), integrate with respect to \(x\), take the imaginary part and sum over all \(k \geq 0\). Then we obtain, by appropriately exchanging indices:

$$\frac{d}{dt} \int_{\mathbb{R}^2} \sum_{k \geq 0} \mu_k |\phi_k|^2 dx$$

$$= \Im \sum_{k \geq 0} \int_{\mathbb{R}^2} \mu_k \left[ H^+ \phi_k + \sum_{l,m,n} \gamma_{lmnk} \phi_l \bar{\phi}_m \phi_n \phi_k \right] dx$$

$$= \Im \int_{\mathbb{R}^2} \sum^* \gamma_{lmnk} \mu_k \phi_k \bar{\phi}_m \phi_l \phi_n dx = \frac{1}{2} \Im \int_{\mathbb{R}^2} \sum^* \gamma_{lmnk} \mu_k + \mu_m \phi_k \bar{\phi}_m \phi_l \phi_n dx$$

$$= \frac{1}{4} \Im \int_{\mathbb{R}^2} \sum^* \gamma_{lmnk} \left[ (\mu_k + \mu_m) \phi_k \bar{\phi}_m \phi_l \phi_n + (\mu_l + \mu_n) \phi_l \bar{\phi}_n \phi_k \phi_m \right] dx$$

$$= \frac{1}{4} \Im \int_{\mathbb{R}^2} \sum^* \gamma_{lmnk} (\mu_k + \mu_m - \mu_l - \mu_n) \phi_k \bar{\phi}_m \phi_l \phi_n dx = 0.$$
2 Global Existence for Finite Sub-Systems

The first step in the numerical approximation of (5) is to cut off the denumerable system at some finite index \( N \). Define \( \Phi := (\phi_k(t, x))_{k \leq N} \), where \( \phi_k \) satisfies:

\[
\begin{align*}
    i\partial_t \phi_k &= H^1 \phi_k + f_k(\Phi), \\
    \phi_k(0, x) &= \phi_k^I(x),
\end{align*}
\]

with \( k \leq N \) and

\[
f_k(\Phi) = \sum_{\mu_n + \mu_l - \mu_m = 0} \gamma_{nmlk} \phi_l \overline{\phi_m} \phi_n.
\]

The method used to show uniqueness and global existence of the finite system works analogously to the proof for the well-posedness of the NLS in the subcritical case [Oh]. For the sake of completeness, we present a brief sketch here.

**Definition 3.** Denote by \((L^p)^N\) the following space:

\[
(L^p)^N = \left\{ \Phi = (\phi_k)_{k \leq N} \mid \phi_k \in L^p(\mathbb{R}^2) \forall k \leq N; \max_{k \leq N} \|\phi_k\|_{L^p(\mathbb{R}^2)} < \infty \right\},
\]

equipped with the maximum norm \( |\Phi|_{(L^p)^N} = \max_{k \leq N} \|\phi_k\|_{L^p(\mathbb{R}^2)} \). Define by

\[
\Sigma := \left\{ \Psi = (\psi_k)_{k \leq N} \mid \sum_{k \leq N} \|\psi_k\|_{H^1(\mathbb{R}^2)}^2 + \sum_{k \leq N} \|x|\psi_k\|_{L^2(\mathbb{R}^2)}^2 < \infty \right\}.
\]

First one has to show by a contraction argument uniqueness and existence of the Cauchy problem on a small time interval \( I \subset \mathbb{R}; |I| < T \) in

\[
\mathcal{X}(I) := C(I, (L^4)^N).
\]

Note that \( \Sigma \) is continuously embedded in \((L^4)^N\). Since the time interval of existence of a local solution with initial data in \( \Sigma \) depends only on the \( \Sigma \)-norm, one can show global existence if one finds an a priori estimate for the \( \Sigma \)-norm of the solution. Notice that the energy is positive. This fact allows then to recover directly estimates for the \( \Sigma \)-norm. In order to prove the conservation laws at a nonnormal level one has to introduce a regularization, which can be removed subsequently by a standard limiting argument. Hereafter we sketch the existence result.

**Theorem 4.** Let \( \Phi^I \in \Sigma \). Then the IVP (8), (9) has a unique solution \( \Phi \) in \( \mathcal{X}(\mathbb{R}) \). Furthermore \( \Phi \in C_b(\mathbb{R}, \Sigma) \) and satisfies the following equalities:

\[
E_1[\Phi^I] = E_1[\Phi(t)], \quad |\Phi^I|_{(L^2)^N} = |\Phi(t)|_{(L^2)^N},
\]

with

\[
E_1[\Phi(t)] := \frac{1}{2} \left[ \|\nabla \Phi(t)\|^2_{L^2(\mathbb{R}^2)} + \|x|\Phi(t)\|^2_{L^2(\mathbb{R}^2)} + \int_{\mathbb{R}^2} \sum_{k \leq N} f_k(\Phi(t, x)) \overline{\phi_k(t, x)} dx \right].
\]
For the proof we proceed as in [Oh]. The following Lemmas and the derived conservation laws provide the tools needed in the proof.

**Lemma 5.** The map \( \Phi \mapsto f(\Phi) \), where \( f(\Phi) = (f_k(\Phi))_{k \leq N} \), is continuous from \((L^4)^N \) to \((L^{4/3})^N \) and satisfies the estimate:

\[
|f(\Phi) - f(\Psi)|_{(L^{4/3})^N} \leq C |\Phi - \Psi|_{(L^4)^N} \left( |\Phi|_{(L^4)^N}^2 + |\Psi|_{(L^4)^N}^2 \right),
\]

where \( C \) is a generic constant and may depend on \( N \).

**Proof.** We easily obtain:

\[
\left| \phi_t \phi_m \phi_n - \psi_t \psi_m \psi_n \right|
\leq \left| \phi_t \phi_m \phi_n - \psi_t \phi_m \phi_n \right| + \left| \psi_t \phi_m \phi_n - \psi_t \psi_m \phi_n \right| + \left| \psi_t \psi_m \phi_n - \psi_t \psi_m \psi_n \right|
= \left| \phi_t - \psi_t \right| \left| \phi_m \phi_n \right| + \left| \phi_m - \psi_m \right| \left| \psi_t \phi_n \right| + \left| \phi_n - \psi_n \right| \left| \psi_m \psi_t \right|
\leq \frac{1}{2} \left[ \left| \phi_t - \psi_t \right| \left( |\phi_m|^2 + |\phi_n|^2 \right) + \left| \phi_m - \psi_m \right| \left( |\psi_t|^2 + |\phi_n|^2 \right) + \left| \phi_n - \psi_n \right| \left( |\psi_m|^2 + |\psi_t|^2 \right) \right],
\]

such that the nonlinearity can be estimated by:

\[
\| f_k(\Phi) - f_k(\Psi) \|_{L^{4/3}} \leq C \sum_{\mu_n + \mu_t - \mu_m - \mu_k = 0, n,l,m \leq N} \gamma_{l,m,n,k} \left[ \left| \phi_t - \psi_t \right| \| \phi_m \|_{L^4}^2 + \| \phi_n \|_{L^4}^2 \right]
+ \left[ \left| \phi_m - \psi_m \right| \| \psi_t \|_{L^4}^2 + \| \phi_n - \psi_n \right| \| \psi_m \|_{L^4}^4 \| \psi_t \|_{L^4}^2 \right].
\]

Summing up over all \( k \leq N \), making use of the symmetry of the indices in the sum over \( \mu_n + \mu_t = \mu_k + \mu_m \), we obtain:

\[
\sum_{k \leq N} \| f_k(\Phi) - f_k(\Psi) \|_{L^{4/3}} \leq C \sum_{\mu_n + \mu_t - \mu_m - \mu_k = 0, n,l,m \leq N} \gamma_{l,m,n,k} \left[ \left| \phi_t - \psi_t \right| \| \phi_m \|_{L^4}^2 + \| \phi_n \|_{L^4}^2 \right]
+ \left[ \left| \phi_m - \psi_m \right| \| \psi_t \|_{L^4}^2 + \| \phi_n - \psi_n \right| \| \psi_m \|_{L^4}^4 \| \psi_t \|_{L^4}^2 \right] \left[ \left| \phi_t \|_{L^4}^2 + \| \phi_m \|_{L^4}^2 + \| \phi_n \|_{L^4}^2 \right) \right]^{1/2}
\leq C \left( \sum_{k \leq N} \| \phi_k - \psi_k \|_{L^4}^4 \right)^{1/2} \left( \sum_{k \leq N} \left[ \left| \phi_t \|_{L^4}^2 + \| \phi_m \|_{L^4}^2 + \| \phi_n \|_{L^4}^2 \right) \right]^{2} \right)^{1/2}
\leq C \left( \sum_{k \leq N} \| \phi_k - \psi_k \|_{L^4}^4 \right)^{1/2} \left( \sum_{k \leq N} \left[ \left| \phi_t \|_{L^4}^2 + \| \phi_m \|_{L^4}^2 \right) \right]^{2} \right)
\leq C |\Phi - \Psi|_{(L^4)^N} \left( |\Phi|_{(L^4)^N}^2 + |\Psi|_{(L^4)^N}^2 \right).
\]
Corresponding to (8) we write the integral equation:

\[ \phi_k(t) = U(t)\phi_k^i + [F_k(0, t)\Phi](t), \]

with \((U(t))_{t \in \mathbb{R}}\) being the group of isometries generated by \(-iH^\perp\) and

\[ [F_k(t_1, t_2)\Phi](t) := i \int_{t_1}^{t_2} U(t - \tau)f_k(\Phi(\tau))d\tau. \]

**Lemma 6.** The map \((t_1, t_2, \Phi) \mapsto F(t_1, t_2)\Phi\) is a continuous map from \(I \times I \times \mathcal{X}(I)\) to \(\mathcal{X}(I)\). Moreover \(F\) satisfies:

\[ |F(t_1, t_2)\Phi - F(t_1, t_2)\Psi|_{\mathcal{X}(I)} \leq C|t_1 - t_2|^{1/2}|\Phi - \Psi|_{\mathcal{X}(I)} \left(|\Phi|^2_{\mathcal{X}(I)} + |\Psi|^2_{\mathcal{X}(I)}\right). \]

**Proof.** As a consequence of Lemma 5 we have for any \(\Phi \in \mathcal{X}(I)\) continuity of the function \(\tau \mapsto f(\Phi(\tau))\). Furthermore we can use information on the operator \(U(t)\), which is actually a bounded operator from \(L^{4/3}\) to \(L^4\), for \(t\) different from zero, such that for \(\Theta \in C(I, (L^{4/3})^N)\) the map \(\tau \mapsto U(t - \tau)\Theta(\tau)\) (where we apply the operator component-wise) is continuous from \(I \setminus \{t\}\) to \((L^4)^N\). Finally the combination of the two maps provides the desired continuity result and we estimate:

\[ \|F(t_1, t_2)\Phi - F(t_1, t_2)\Psi\|_{L^4} \]

\[ \leq \sum_{k \leq N} \|[F_k(t_1, t_2)\Phi - F_k(t_1, t_2)\Psi](t)\|_{L^4} \]

\[ \leq \sum_{k \leq N} \int_{t_1}^{t_2} \|U(t - \tau)[f_k(\Phi(\tau)) - f_k(\Psi(\tau))]\|_{L^4}d\tau \]

\[ \leq \sum_{k \leq N} \int_{t_1}^{t_2} |t - \tau|^{-1/2}\|f_k(\Phi(\tau)) - f_k(\Psi(\tau))\|_{L^{4/3}}d\tau \]

\[ = \int_{t_1}^{t_2} |t - \tau|^{-1/2}\sum_{k \leq N} \|f_k(\Phi(\tau)) - f_k(\Psi(\tau))\|_{L^{4/3}}d\tau \]

\[ \leq |t_1 - t_2|^{1/2}\|f_k(\Phi) - f_k(\Psi)\|_{C(I, (L^{4/3})^N)}\].

The statement is then a consequence of Lemma 5. \(\square\)

### 3 Numerical Approximation

In this section we describe the method used to numerically solve the asymptotic approximation (5) of the GPE with strongly anisotropic potential. We have already seen in the first part of this work that in the limit \(\varepsilon\) to zero ('infinite' confinement in \(z\)-direction) we formally obtain a system of GPEs. To treat the system numerically we truncate the expansion at a finite index \(N\) and consider only a finite number of limiting equations (8). Moreover we consider here a spatial dimension reduction from 2D to 1D, for which
the theory developed in the previous sections applies just as for the presented case of reduction from 3D to 2D. In other words we consider the following rescaled GPE:

\[ i\psi_t = H^\perp \psi + \frac{1}{\varepsilon^2} H \psi + |\psi|^2 \psi, \quad (13) \]

\[ \psi(0, x, z) = \psi^0(x, z), \quad x, z \in \mathbb{R}. \]

In order to solve the GPE (13) (for benchmark tests), we use the time-splitting spectral method (TSSP), as presented in [BJM].

For \( N=1 \), we have only one equation in the limiting system:

\[ i\partial_t \phi_0 = H^\perp \phi_0 + \gamma_{0000} |\phi_0|^2 \phi_0, \quad (14) \]

\[ \phi(0, x) = \phi_0^0(x), \quad x \in \mathbb{R}, \quad (15) \]

where

\[ \gamma_{klmn} = \int_{\mathbb{R}} \omega_k(z) \omega_l(z) \omega_m(z) \omega_n(z) dz, \]

\( (\mu_k, \omega_k) \) is the \( k \)-eigenpair satisfying

\[ \frac{1}{2} (-\partial_{zz} + z^2) \omega_k(z) = \mu_k \omega_k(z), \]

with \( \omega_k \) normalized to 1 in \( L^2(\mathbb{R}) \).

For \( N = 2 \), we have following limiting coupled system:

\[ i\partial_t \phi_0 = H^\perp \phi_0 + (\gamma_{0000} |\phi_0|^2 + 2\gamma_{0011} |\phi_1|^2) \phi_0, \quad (16) \]

\[ i\partial_t \phi_1 = H^\perp \phi_1 + (2\gamma_{0011} |\phi_0|^2 + \gamma_{1111} |\phi_1|^2) \phi_1, \quad (17) \]

It is obvious that for both cases, \( N = 1 \) [BJM] and \( N = 2 \) [B] respectively, we can use (the Strang-splitting version of) TSSP for discretizing the system in a straightforward way, since both equations are of NLS-type such that the moduli of the wave functions \( \phi_0 \) and \( \phi_1 \) are conserved in the potential-splitting step.

On the other hand, if we consider \( N = 3 \) we have:

\[ i\partial_t \phi_0 = H^\perp \phi_0 + (\gamma_{0000} |\phi_0|^2 + 2\gamma_{0011} |\phi_1|^2 + 2\gamma_{0022} |\phi_2|^2) \phi_0 + \gamma_{0112} \phi_1^2 \phi_2, \]

\[ i\partial_t \phi_1 = H^\perp \phi_1 + (2\gamma_{0011} |\phi_0|^2 + \gamma_{1111} |\phi_1|^2 + 2\gamma_{1122} |\phi_2|^2) \phi_1 + 2\gamma_{0112} \phi_0 \phi_1 \phi_2, \]

\[ i\partial_t \phi_2 = H^\perp \phi_2 + (2\gamma_{0022} |\phi_0|^2 + 2\gamma_{1122} |\phi_1|^2 + \gamma_{2222} |\phi_2|^2) \phi_2 + \gamma_{0112} \phi_0 \phi_1 \phi_2. \]

For \( t \in [t_n, t_{n+1}] \) we discretize this system of 3 equations by splitting it in three subsystems which we are going to solve in 5 steps:

Step 1). For the time step of length \( \Delta t/2 \) we solve:

\[ i\partial_t \phi_0 = \left( \frac{x^2}{2} + \gamma_{0000} |\phi_0|^2 + 2\gamma_{0011} |\phi_1|^2 + 2\gamma_{0022} |\phi_2|^2 \right) \phi_0, \]

\[ i\partial_t \phi_1 = \left( \frac{x^2}{2} + 2\gamma_{0011} |\phi_0|^2 + \gamma_{1111} |\phi_1|^2 + 2\gamma_{1122} |\phi_2|^2 \right) \phi_1, \]

\[ i\partial_t \phi_2 = \left( \frac{x^2}{2} + 2\gamma_{0022} |\phi_0|^2 + 2\gamma_{1122} |\phi_1|^2 + \gamma_{2222} |\phi_2|^2 \right) \phi_2. \]
Since for this time step each ODE leaves $|\phi_0|$, $|\phi_1|$ and $|\phi_2|$ invariant in time, we can integrate each equation (separately) exactly in time, given initial data at $t_n$.

Step 2). For the time step of length $\Delta t/2$ we solve:

\[
\begin{align*}
  i\partial_t \phi_0 &= -\frac{1}{2} \Delta_x \phi_0, \\
  i\partial_t \phi_1 &= -\frac{1}{2} \Delta_x \phi_1, \\
  i\partial_t \phi_2 &= -\frac{1}{2} \Delta_x \phi_2,
\end{align*}
\]

by using the Fourier pseudospectral discretization in space and then integrating the ordinary differential system (ODEs) in phase space exactly in time.

Step 3). For the time step of length $\Delta t$ we solve:

\[
\begin{align*}
  i\partial_t \phi_0 &= \gamma_{0112} \phi_1^2 \bar{\phi}_2, \\
  i\partial_t \phi_1 &= 2\gamma_{0112} \phi_0 \phi_2 \bar{\phi}_1, \\
  i\partial_t \phi_2 &= \gamma_{0112} \phi_1^2 \bar{\phi}_0,
\end{align*}
\]

Here we discuss in detail how we implement the discretization of (18). We can rewrite this system as:

\[
\partial_t \Psi = \gamma_{0112} A_r(\Psi)\Psi,
\]

where $\Psi := (\Re(\phi_0), \Im(\phi_0), \Re(\phi_1), \Im(\phi_1), \Re(\phi_2), \Im(\phi_2))^T = (\psi_0, \psi_1, \psi_2, \psi_3, \psi_4, \psi_5)^T$ and

\[
A_r(\Psi) := \begin{pmatrix}
  0 & 0 & 0 & 0 & 2\psi_2\psi_3 & \psi_3 - \psi_2 \\
  0 & 0 & 0 & 0 & 2(\psi_0\psi_5 + \psi_4\psi_1) & 0 \\
  0 & 0 & 0 & 0 & 2(\psi_1\psi_5 - \psi_0\psi_4) & -2(\psi_0\psi_5 + \psi_4\psi_1) \\
  2\psi_2\psi_3 & \psi_3 - \psi_2 & 0 & 0 & 0 & 0 \\
  \psi_3 - \psi_2 & -2\psi_2\psi_3 & 0 & 0 & 0 & 0
\end{pmatrix}.
\]

Integrate (19) over the time interval $[t_n, t_{n+1}]$, approximate the integral by the trapezoidal quadrature, we get

\[
\Psi(t_{n+1}) = e^{\gamma_{0112} \int_{t_n}^{t_{n+1}} A_r(\Psi(\tau))d\tau} \approx e^{\gamma_{0112} \frac{\Delta t}{2} [A_r(\Psi(t_n)) + A_r(\Psi(t_{n+1}))]}
\]

\[
\approx e^{\gamma_{0112} \frac{\Delta t}{2} [A_r(\Psi^n) + A_r(\Psi^{(1)})] : = e^{\gamma_{0112} \Delta t \tilde{A}_r(\Psi^n)},
\]

where $\Psi^{(1)}$ is an approximation of $\Psi(t_{n+1})$ and can be computed from the ODEs (19) by any explicit method. Here we use the Forward Euler method to compute it as:

\[
\Psi^{(1)} = \Psi^n + \Delta t \gamma_{0112} A_r(\Psi^n) \Psi^n, \quad \tilde{A}_r(\Psi^n) = \frac{1}{2} [A_r(\Psi^n) + A_r(\Psi^{(1)})].
\]

Since $\tilde{A}_r$ is symmetric and sparse, we can find explicitly an orthogonal matrix $P$ with $P^{-1} = P^T$ and a diagonal matrix $\Lambda$ such that

\[
\tilde{A}_r = P \Lambda P^{-1} = P \Lambda P^T.
\]
Thus we can compute one-step approximation of the ODEs (19) as

$$\Psi^{n+1} = P \ e^{\gamma_{0112} \Delta t} \ P^T \ \Psi^n.$$ 

After getting $\Psi^{n+1}$, it is straightforward to recover the approximation $\Phi^{n+1}$ for the ODEs (18).

**Remark** In terms of $\Phi = (\phi_0, \phi_1, \phi_2)^T$, it is then obvious that we have mass conservation (the absolute value of $\Phi$ is conserved).

Step 4). For the time step of length $\Delta t/2$ we solve again:

$$i \partial_t \phi_0 = -\frac{1}{2} \Delta_x \phi_0,$$

$$i \partial_t \phi_1 = -\frac{1}{2} \Delta_x \phi_1,$$

$$i \partial_t \phi_2 = -\frac{1}{2} \Delta_x \phi_2.$$

Step 5). For the time step of length $\Delta t/2$ we solve again:

$$i \partial_t \phi_0 = \left(\frac{x^2}{2} + \gamma_{0000} |\phi_0|^2 + 2 \gamma_{0011} |\phi_1|^2 + 2 \gamma_{0022} |\phi_2|^2\right) \phi_0,$$

$$i \partial_t \phi_1 = \left(\frac{x^2}{2} + 2 \gamma_{0011} |\phi_0|^2 + \gamma_{1111} |\phi_1|^2 + 2 \gamma_{1122} |\phi_2|^2\right) \phi_1,$$

$$i \partial_t \phi_2 = \left(\frac{x^2}{2} + 2 \gamma_{0022} |\phi_0|^2 + 2 \gamma_{1122} |\phi_1|^2 + \gamma_{2222} |\phi_2|^2\right) \phi_2.$$

For $N = 4$ we can use the analogous type of discretization as in the case of $N = 3$. Writing the system for $N = 4$ explicitly we immediately realize that the matrix $A_r$ is symmetric and sparse.

We remark that the presented time splitting-spectral technique for $N = 1, 2, 3, 4$ is second order in time and of spectral accuracy in space.

## 4 Numerical examples

**Example 1** For $N = 1$, i.e. in the case of one limiting equation, we choose as initial condition for (13)

$$\psi^f(x, z) = \omega_0(z) \phi_0^f(x)$$

and solve the IVP on $[-8, 8] \times [-a_z, a_z]$ with periodic boundary conditions. Secondly, we solve (14) with initial condition

$$\phi_0(0, x) = \phi_0^g(x) = \left(\frac{1}{\pi}\right)^{1/4} \ e^{-x^2/2},$$

on $[-8, 8]$ with periodic boundary conditions. $N_x$ denotes the number of grid points in $x$-direction, $N_z$ denotes the number of grid points in $z$-direction and $\Delta t$ the time step. The numerical values for the experiment set-up can be seen in Table 1.
\[
\begin{array}{|c|c|c|c|c|}
\hline
\varepsilon & a_z & N_z & N_x & \Delta t \\
0.8 & 6 & 128 & 256 & 10^{-3} \\
0.4 & 3 & 128 & 256 & 10^{-3} \\
0.2 & 1.5 & 256 & 512 & 10^{-4} \\
0.1 & 0.8 & 256 & 512 & 10^{-4} \\
0.05 & 0.4 & 256 & 512 & 10^{-5} \\
\hline
\end{array}
\]

Table 1: Values for the parameters used in numerical experiments.

Figure 1: \( \sigma^\varepsilon(t) \) with \( \varepsilon = 0.8, 0.4, 0.2, 0.1 \) and \( 0.05 \) (in the order of decreasing peaks).

In Figure 1, we plot the \( L^2 \) norm of the approximation error as function of time, with final time \( t = 5 \), i.e.

\[
\sigma^\varepsilon(t) = \| \psi(., . , t) - \phi_0(., t)\omega_0(.)e^{-i\mu t/\varepsilon^2} \|_{L^2(\mathbb{R}^2)},
\]

for different \( \varepsilon \).

From Fig. 1, we can see that when \( \varepsilon \) decreases by half to \( \varepsilon/2 \), the error decreases by half too, and the oscillation frequency of the error increases four times.

**Example 2** For \( N = 2 \), i.e. in the case of two equations (16), we choose initial data as

\[
\begin{aligned}
\phi_0(0, x) &= \phi_1^I(x) = \left( \frac{1}{\sqrt{2}} \right) \left( \frac{1}{\pi} \right)^{1/4} e^{-x^2/2}, \\
\phi_1(0, x) &= \phi_1^I(x) = \sqrt{2} x \phi_0^I,
\end{aligned}
\]

and solve the coupled system of GPEs on the \( x \)-interval \([ -8, 8 ]\) subject to periodic bound-
ary conditions. The initial condition for (13) is taken as:

$$\psi^J(x, z) = \omega_0(z)\phi_0^J(x) + \omega_1(z)\phi_1^J(x)$$

with $\phi_0^J$ and $\phi_1^J$ as in (20). As before we solve the 2D GPE $[-8, 8] \times [-a_z, a_z]$ subject to periodic boundary conditions. Furthermore we consider the same experimental set-up as before (see detail in Tab. 1) and plot in Figure 2 the following quantity for different values of $\varepsilon$:

$$\sigma_2^\varepsilon(t) = \|\psi(., ., t) - \sum_{k=0}^1 \phi_k(., t)\omega_k(\cdot)e^{-i\mu_k t/\varepsilon^2}\|_{L^2(\mathbb{R}^2)}.$$  

**Example 3** For $N = 3$, we proceed analogously for the coupled system (18) of three GPEs. We choose initial conditions as

$$\begin{align*}
\phi_0(0, x) &= \phi_0^f(x) = \left(\frac{1}{\sqrt{3}}\right) \left(\frac{1}{\pi}\right)^{1/4} e^{-x^2/2}, \\
\phi_1(0, x) &= \phi_1^f(x) = \sqrt{2} x \phi_0^f, \\
\phi_2(0, x) &= \phi_2^f(x) = \frac{1}{\sqrt{8}}(4x^2 - 2) \phi_0^f,
\end{align*}$$

and solve on the $x$-interval $[-8, 8]$ subject to periodic boundary conditions. Then we choose initial datum for (13) as:

$$\psi^J(x, z) = \omega_0(z)\phi_0^J(x) + \omega_1(z)\phi_1^J(x) + \omega_2(z)\phi_2^J(x),$$

with $\phi_0^J, \phi_1^J$ and $\phi_2^J$ as in (21), and solve as before on $[-8, 8] \times [-a_z, a_z]$ subject to periodic
boundary conditions. Analogously to \( N = 1, 2 \) we depict in Figure 3 the error:

\[
\sigma^\varepsilon_k(t) = \| \psi(\cdot, \cdot, t) - \sum_{k=0}^{2} \phi_k(\cdot) \omega_k(\cdot) e^{-i \mu_k t \varepsilon^2} \|_{L^2(\mathbb{R}^2)}.
\]

From Figs. 1-3, we can draw the following conclusions: i) When \( N = 1 \), the approximation error clearly ’tends to 0’ as \( \varepsilon \) ’tends to zero’ (cf. Fig. 1). ii) When \( N = 2, 3 \), the approximation error decreases when \( \varepsilon \) decreases and is not too small. When \( \varepsilon \) is small, it stabilizes at some nonzero values although \( \varepsilon \) is still decreasing (cf. Figs. 2&3). This is due to the fact that no other Fourier terms are generated for \( N = 1 \), while all Fourier terms (with indices \( k > 0 \)) appear instantaneously for \( N = 2, 3 \).

**Example 4** Finally, we compare for fixed values of \( \varepsilon \) the functions \( \sigma^\varepsilon_k(t) \), \( \sigma^\varepsilon_2(t) \) and \( \sigma^\varepsilon_3(t) \), where \( \psi(t) \) is solved with initial data (22). Figure 4 shows these functions and a reference GPE-solution \( |\psi(t = 5)|^2 \) computed with the initial datum (22) for different \( \varepsilon \).

From Fig. 4, we can observe that: i) the reference solution concentrates more and more in the \( z \) direction as \( \varepsilon \) tends to zero; ii) the more Fourier terms are considered in the approximation, the smaller the approximation error becomes; iii) when \( N \) is fixed, the approximation error doesn’t decrease when \( \varepsilon \) is decreasing but small, i.e. this implies that expansion error becomes dominant when \( \varepsilon \) is sufficiently small. In fact, the approximation error consists of two parts: one is from the truncation error, and the other is from the anisotropic confinement.
Figure 4: Surface plots (left column) of the position density $|\psi(x, t = 5)|^2$ and the approximation errors $\sigma_1^\varepsilon(t)$ (blue), $\sigma_2^\varepsilon(t)$ (red), $\sigma_3^\varepsilon(t)$ (black) (right column) for different $\varepsilon$: a) $\varepsilon = 0.8$; b) $\varepsilon = 0.4$; c) $\varepsilon = 0.2$; d) $\varepsilon = 0.1$.
